Planning for Transition

Contemporary cities and territories face significant challenges – natural disasters due to climate change impacts, ecological crises, growing socio-economic unrest, global migration, political rifts including a rise of right wing factions, ambitious public works and mega-projects – all of which require new capacities in dealing with such individual and multiple groupings of such challenging and profound changes.

It is a matter of fact that at international level a discourse if not a condition of transition is pervading sectors and societies. This discourse points to alternative patterns and solutions to many of the challenges faced. A quickly changing scenario requires forms of planning, both locally and globally, which bear the capacity to support and manage mutable urban and environmental conditions. In fact, although cities do incessantly change, policy-makers and institutions are never fully prepared to respond to complex and risky situations, as well as relying on planning and policy tools which are often outdated; in addition, also existing theoretical frameworks, concepts, cognitive abilities and approaches become ineffective or outmoded.

Each unintended or unanticipated change comes as a break to existing social, political, and administrative routines and yet it may be anticipated that mechanisms of collective reflection and action will be generated. The congress invites scholars and practitioners to present and discuss case-studies of cities and projects that have engaged in meeting challenging situations – supporting transitions in urban contexts.

Specifically, it is aimed at offering an understanding of the forms of knowledge, concepts, tools, and skills needed to plan and address transition. Furthermore, it seeks to explore whether (and how) managing such changes has brought any overall reconsideration of the city design model and towards more general institutional reconfigurations.

The book collects all the papers presented at the Aesop Venice 2019 conference.

It is articulated in chapters that correspond to the tracks (16) and special sessions proposed (23).

Tracks

1. Transforming built heritage and landscapes
2. Urban design for multilevel planning
3. Teaching planning for the transition
4. Institutional change and regional transition
5. Methods and technologies for transformative planning
6. Community-based planning and social innovation
7. Theorizing urban change: complexity and ethics
8. Transition paths and urban futures
9. Climate proof cities and resilient societies
10. Urban metabolism and circular economy
11. Housing, gentrification and socio-spatial dynamics
12. Food, planning and healthy cities
13. Planning for accessibility and sustainable mobility
14. Planning, Law and Property Right: facing urban transitions
15. Tourism, spaces and urban cultures
16. Urban and Regional economics for transition

Special Session

1. Transition Histories
2. Urban Tourism, Neighborhood Change and Social Conflicts
3. Innovative Agriculture for Healthy Cities
4. Towards Post-Growth Planning Theory and Practice
5. Planning and Designing Green Infrastructures
6. Land Development and Management in Post-Socialist Countries
7. Home Sharing. Short-Term Rentals Affecting Local Housing Markets
8. Dynamic Change, Uncertainty and Planning for Adaptivity
9. Space, Citizenship and Identity: The Eu-Mena Region
10. The Role of The Local in Improving Cohesion and Spatial Justice
11. Friendly Spaces and Mobility for Ageing
12. Emerging Spatialities and Eu Policy Instruments: Cases and Perspectives
13. Facing Migrants Exclusionary Urban Policies
14. Learning Loops in The Public Realm. Enabling Social Learning in Communities to Tackle the Challenges of Cities in Transition
15. Planning and Biodiversity
16. Acsp-Aesop Special Session: Morsels of Hope: Migration and Urban Planning
17. Spatial Tensions: Urban Microgeographies for Changing Cities
18. Affordable Housing in Developing Countries: a Comparative Perspective
19. Acsp-Aesop Special Session: Learning from Arnstein's Ladder: from Citizen Participation to Public Engagement
20. Smart Cities and Regions Informing the Energy Transition
21. Maritime Spatial Planning (MSP) In Europe: Challenges in Transition
22. Shrinking Cities and Sustainability
23. Regional Design: Impacts on Territorial Governance and Planning Practice

Abstract: Due to worldwide changes in economic conditions and industrial infrastructures, many coastal industrial areas are now suffering from the outflows of industry and population. In recent years, efforts aimed at halting such declines and revitalizing those areas have often been led by cultural and artistic activities. One such effort is the “Setouchi Art Festival” on islands in Japan’s Seto Inland Sea. On Inujima, one of them, the Inujima Seirenscho Art Museum was built on the ruins of an old copper refinery as a tribute to the island’s industrial heritage. A number of other art projects were created on the island and old houses were renovated as part of the art festival. This paper aims to identify the influence of these creative activities on the island’s residents and learn how they reflect the conservation of culture, history, and the natural landscape of Inujima Island. To accomplish this, we conducted a field survey and interviews with local residents and learned that many of them feel positive about interacting with the young people who visit the art festival, including foreign tourists, while other local residents have developed a sense of separation from the old refinery since it was transformed into an art museum.

Keywords: heritage; artistic activities; Setouchi Art Festival; islands

1. Introduction

In Japan, huge coastal industrial areas were formed along with the rapid development of the heavy chemical industries during the rapid economic growth that began in the 1960s. However, due to the worldwide changes in economic conditions and industrial infrastructure, many of those coastal areas are now experiencing significant outflows of industry and population, which means that local economic conditions are now facing serious problems (Abe, 2017).

In many places, efforts aimed at promoting sustainable development in such declining areas are led by creating and revitalizing industries that focus on cultural and artistic activities (Lee *et al.* 2017). One such effort is the “Setouchi Art Festival”, which has been attracting numerous tourists over the last ten years. Although many of the Setouchi islands, a geographic region in Japan that includes the Seto Inland Sea, prospered during the years when the copper mining and refining industries were influential, many of those

factories have since closed and the islands that hosted them are now facing the related problems of depopulation and aging residents.

In response to those circumstances, Soichiro Fukutake, former Chairman of the Benesse Corporation and Chairman of the Naoshima Fukutake Art Museum Foundation, has led an effort to revitalize these areas. Focusing initially on four islands, he enlisted the aid of famous architects and artists in efforts to build art museums, hotels, and recreational facilities. Through his efforts, and with the assistance of the Kagawa Prefecture and Takamatsu City governments, the Setouchi Art Festival had spread to seven islands by 2010, and had been attended by more than ten million people by 2016.

However, since excessive dependence on government funding for such activities could result in difficulties during times when budgets are lean, it is hoped that those abovementioned activities will eventually become self-sustaining and develop in ways that allow culture, history, and natural landscapes of those islands to be conserved. With that point in mind, this paper aims at identifying the influence of these creative activities on the residents and determining their effectiveness in preserving local culture, history, and landscape. Specifically, we selected Inujima Island from among the seven participating islands of the Setouchi Art Festival and conducted a field survey there along with interviews with local residents.

2. Setouchi Art Festival

The “Setouchi Art Festival” is a modern art festival held on the Setouchi islands once every three years beginning in 2010, so it has been held three times so far. Although the festival’s executive committee is composed of many local organizations, its primary members are regional and local authorities such as Kagawa Prefecture, Takamatsu City, and the Fukutake Foundation. In 2010, the festival was held at Naoshima, Teshima, Megijima, Ogijima, Shodoshima, Oshima, Inujima, and Takamatsu Port. It has since been held on a total of 12 islands and two ports, including Shamijima, Honjima, Takamijima, Awashima, Ibukijima, and Uno Port.

Figure 1. Setouchi Art Festival locations (Setouchi Triennale 2019, 2018)

The festival’s exhibitions consist of modern artworks such as paintings and sculptures, visual media, performances, and architecture in harmony with natural landscapes. A total of 938,246 people visited the first festival in 2010, 1,070,368 people visited in 2013, and 1,040,050 people visited in 2016. The figures in Table 1 show the total income and expenditures for the festival from 2010 to 2016. Here, it can be seen that Kagawa Prefecture, the Fukutake Foundation, and another city paid an almost half of the total expenditures. Furthermore, it can be seen that Kagawa Prefecture and the Fukutake Foundation account for a third of those expenditures, while subsidies and donations account for another fourth. The remaining expenses were met with revenues from the sales of goods or tickets.

The Expenditure table also shows the costs of the art projects. Although the festival has continued to expand, the proportion of revenues obtained from tickets and goods has not changed, even though the

related expenditures increase each time it is held. In the period since 2013, total expenditures have increased by 47%.

money carried forward to the next year		3	118	0	121	54	162	160		51	239	150	
total		26	229	555	810	73	550	768		85	701	892	

Table 2. Expenditures of Setouchi Art Festival from 2010 to 2016 (million) (The Setouchi Art Festival Committee, 2010, 2013 and 2016)

From Table 1, it can be seen that burden charges account for about half of the income and the proceeds account for less than a quarter of the income in 2014-2016. In addition, it can be seen that the subsidies and donations account for a third of the income in 2014-2016. From Table 2, it can be seen that the art project costs, especially production costs, account for more than half of the expenditures.

From the above, it can be seen the Setouchi Art Festival is heavily dependent on outside funding. This is suboptimal because there are many calls for such outside funds and the festival might not be chosen for support in times when budgets are lean. Hence, increases in self-generated revenues and improvements in the financial cycle of the festival are urgently needed.

3. Art Projects in Inujima

Inujima, which once had a population of about 6,000 people, is one of the islands that prospered during the time when copper quarrying and refining were major industries. However, both of those industries

have since declined, and the average age of an island resident is now about 75 years old. Furthermore, the population has sharply declined to just 50 people. In an effort to revitalize the island while paying homage to its industrial heritage, the Inujima Art Museum was built on the foundations and surviving structures of an old copper refinery. Additionally, a number of art projects were created and old houses were renovated as part of the art festival.

Of a number of art projects launched in Inujima, the most famous three projects are explained as follows.

Figure 2. Map of Inujima

3.1 Inujima Seirenscho Art Museum

Based on the concept of “Utilizing existing elements and creating elements that do not exist,” the Inujima Seirenscho Art Museum conserved and restored the ruins of a former copper refinery in Inujima. The present-day facility, which introduced the architecture of Hiroshi Sambuichi, was designed to utilize existing chimneys and Karami bricks and to take advantage of natural energy sources such as sunlight and geothermal heat, thus minimizing the museum’s environmental impact. Artwork by Yukinori Yanagi based on a motif of Yukio Mishima (a famous Japanese author) and a high-efficiency plant-based water purification system were included as well. With careful attention paid to such elements as heritage, architecture, art, and the natural environment, this museum embodies the consciousness of a recycling-oriented society (Benesse Art Site Naoshima, 2018).

Figure 3. Seirenscho Art Museum

Figure 4. Circulation of Seirenscho Art Museum

(Benesse Art Site Naoshima, 2018)

3.2 Inujima Art House Project

This Inujima village project was developed by artistic director Yuko Hasegawa and architect Kazuyo Sejima. Artworks are exhibited in refurbished “art house” galleries scattered around the island so that visitors can also experience the beauty of the natural landscape as they meander from house-to-house while interacting with each other and villagers engaged in their usual everyday lives. The galleries dotting the village were constructed from various material such as the roof tiles and beams of old houses. In some places, transparent acrylic and aluminum panels have been installed to showcase the surrounding natural landscape. This provides visitors with opportunities to walk in places where they can appreciate the beauty of Inujima while also enjoying the exhibitions (Benesse Art Site Naoshima, 2018).

Figure 8. A-Art House, “Yellow Flower Dream”

Figure 9. C-Art House, “Ether”

Figure 10. “Former site of a stonecutter’s house”

(Benesse Art Site Naoshima, 2018)

3.3 Inujima Life Garden

The Inujima Life Garden is another Inujima Landscape Project created by Sejima. For this permanent facility, she revived a long-abandoned glass-paned greenhouse and developed a small park and botanical

garden around it that are rooted in the island's climate and culture. She envisions the garden as a space in which it is possible to design a new lifestyle by experiencing self-sufficient living within the island's rich natural environment (Benesse Art Site Naoshima, 2018).

4. Interviews with local residents and management representatives of the Setouchi Art Festival

We conducted interviews with nine people, including local residents and the management representatives of the Setouchi Art Festival, on the following five points:

- (1) Changes of the attachment to Inujima and lifestyles before and after the festival
- (2) Artworks
- (3) Advantages and disadvantages of the festival
- (4) Relationships with tourists
- (5) Issues and future perspectives

	gender	age	occupation	When live in Inujima?	How long live?	Who live with?	Where go shopping?
A	male	70's	pension	before the festival	more than 5 years	couple	out of the island

Table 3. Local Resident Data

Interviewee A is a pensioner, as well as a leader of the Inujima Community Association. He lives on the island with his wife and provides leadership to the festival. Although originally from one of the Setouchi Islands belonging to Hiroshima Prefecture, he came to Inujima because it is where his wife lives.

Neither my attachment with this island nor my lifestyle has changed because the tourists only stay for two or three hours during the day and the island becomes as quiet as usual at night. Besides, there are no workplaces, nursery schools, elementary schools, or junior high schools here, so even if you wanted to move here, you could not stay on the island full-time.

When Mr. Fukutake asked me to cooperate with the neighborhood association for the Setouchi Art Festival, I told him I'd give him as much help as I could. He created employment opportunities for islanders up to three hours a day doing such chores as planting flowers, but we do not sell things made from Inujima resources, so the festival economically influences the island.

Regarding the art, it may be impressive to some, but there are many artworks I simply cannot understand. But that's natural because priorities between the aged and young are different, as are their understandings. One issue about the Setouchi Art Festival that needs improvement is that we do not have good verbal communication with foreign visitors because of a lack of interpreters.

Nevertheless, we are grateful to the festival just for increasing the number of people that know about Inujima. I think the festival will continue in the future. Of course, the continuation of the festival depends on the commitment of Mr. Fukutake, but I think his son will follow his example.

Interviewee C is a man working at the Trees Café who stays on Inujima most of the week, but has not yet completely moved to the island.

I originally came here to participate in Inujima events, but I came to know the owner of this café who asked me to help here. This island is a quiet and calm place.

Interviewee D was born in Inujima and worked in other locations in Okayama Prefecture, but came back to Inujima to provide care for his aged father.

I think the Inujima Seirenscho Museum is very good, but the location does not have the same connection to the residents it had before. Regarding interactions with visitors, I sometimes inform tourists about how to find the art houses and give them some basic explanations regarding them because there is not any posted information or explanations. For example, sometimes it is necessary to let tourists know that they can enter the galleries freely because there are no signs indicating that they can go inside. Sometimes I also tell them how to view the artworks, but I am often troubled providing explanations to foreigners.

Since the Setouchi Art Festival is centered in Kagawa Prefecture, Okayama Prefecture does not provide financial help to Inujima and Okayama Prefecture residents on Inujima feel somewhat abandoned. We want Okayama Prefecture to help Inujima, too, and I want the festival to continue as long as possible. However, since we do not have the resources to operate the festival by ourselves, it depends on Mr. Fukutake's generosity.

Interviewee E was originally a staff member for an event held on Inujima who decided he wanted to live on the island and moved to Inujima with his wife B four years so. Now, they run Ukicafe.

We love Inujima because of its charms such as its quiet and relaxing atmosphere – not because of its artworks. However, the festival influences people whether they are running their own café or working at the museum.

Interviewee F is a pensioner who was born in Inujima, left to find work, and returned 30 years ago. He currently works part time.

Since the start of the festival, Inujima has recovered more energy than it had before, but my attachment with this island has never changed. I feel it is a little noisy during the day, but usually quiet and relaxed at night. My part-time job for Benesse Corp. is mainly mowing. The festival has never influenced us. Besides, it is very questionable whether the old refinery should have been renovated into the Seirenscho Art Museum.

The former refinery was sufficiently beautiful, but now we cannot enter the facility site freely because it was purchased by Mr. Fukutake. I think the buildings are good, but I cannot understand the artworks. Regarding interactions with visitors, I talk sometimes to the tourists because I can understand English if it is spoken slowly, but cannot speak Korean or Chinese.

Interviewee G is an employee of a lodging company in Inujima. A number of the employees work in shifts so they can always respond to guests.

Members of the theatrical groups and the architects usually stay here. Sometimes foreigners do too. There are also a few guests that are here to enjoy astronomy. However, almost all of the guests want to see the artworks or participate in events for children.

Interviewees H and I are employed by the Seirenscho Art Museum and commute to work without living in the island.

Okayama City is not very much involved in the Setouchi Art Festival. In Inujima, new houses cannot be built because of strong resistance from Okayama City, so the number of immigrants does not increase.

Summary of interviews with local residents and the festival's managers

- The festival has not changed local residents' lifestyles and attachments for Inujima significantly.
- The festival has attracted several migrants to Inujima, but they live on the island because of its intrinsic charms, not because of the artworks.
- The refinery's relationship with the local residents has become more distant since it became a museum.
- Okayama City does not provide much support to Inujima.
- The local residents are grateful to the festival for providing interactions with young people and foreigners. They hope the festival will continue.

5. Interviews with visitors to Inujima

We conducted interviews on the following three points with six visitors:

- (1) Inujima art projects
- (2) The Setouchi islands they have visited and will visit, and their trip routes
- (3) Opinions about the Setouchi Art Festival

	gender	age	occupation	address	transit port	companion	Where stay at?
J	male	20's	student	Kinki	Houden Port	friends	no
K	femae	30's	employee	Kantou	Naoshima/Teshima	alone	no
L	male	70's	retirement	Kinki	Houden Port	friends	no
M	male	30's	employee	Cyugoku	Houden Port	alone	no
N	femae	60's	part-time job	Cyugoku	Houden Port	family	no
O	male	20's	employee	Cyugoku	Naoshima/Teshima	friends	no

Table 4. Visitor Data

Visitor J said,

I want to come here again, but I would not want to move here, because this island is difficult to visit and does not have any convenience stores. I wish it was more accessible. The Seirenscho Art Museum is good and within my expectations. The museum educated me on historical contexts through the renovation of the refinery.

The Art House Project was normal, but Inujima Life Garden was very good. I talked with an elderly man that owns a colored carp. He was very friendly. However, I thought Inujima was an island that does not have a lived-in feel because there are so few residents.

Visitor K said,

I want to come here again and would like to live here for a limited period. I think it is good that the museum is made using an existing building. I get a sense that history has continued without destroying the past. I could understand the F-Art House, but I could not understand the others.

Visitor O said,

I think I want to come here again in several years in order to find how Inujima has changed. I hope to live on an island in the future, so I think moving to Inujima would be a good choice.

Summary of interviews with the visitors

- There are many who would like to move to Inujima if the island had better facilities. This is related to the point that it is currently too difficult to increase the number of immigrants.
- Inujima's attractions are not limited to the artworks; they also include the enhancement of atmosphere and scenic nature of the island, as well as the local residents' behavior towards visitors.

6. Conclusions

In this paper, we aimed at identifying the influence of creative activities such as Setouchi Art Festival and the creation of the Seirenscho Art Museum on the island's residents in an effort to learn how they reflect the conservation of culture, history, and the natural landscape of Inujima Island, and how they are perceived by both the residents and visitors to Inujima.

The paper results can be summarized as follows:

1. It was revealed that there were few changes in resident lifestyles and their attachments to the island as a result of the Setouchi Art Festival.
2. It was revealed that the number of people who have come to know about Inujima has increased because of the festival, but it is currently too difficult to increase the number of immigrants. Improvements to the basis of the island's livelihood and facilities will be needed in order to increase the number of immigrants.
3. It was revealed that the people who live in Inujima, or want to move there, like the island regardless of the artworks. Furthermore, it has become clear that one reason the number of immigrants will not increase easily is there is a strong policy of Okayama City to restrict new housing construction.
4. Most local residents have somewhat comfortable lives due to their pensions and wages resulting from Benesse Corp. employment opportunities, but they do not think there have been any significant economic effects as a result of the festival.
5. It was revealed the many visitors are satisfied by seeing the things that have long existed on the island that they would not have had a chance to learn about without the festival. It was further revealed there many people like the atmosphere of the island, which means that one of the purposes of the Setouchi Art Festival, helping others to discover the attractive characteristic of the islands, has been achieved, even though some of the residents regret losing familiarity with the refinery since it was converted into a museum.
6. The local residents appreciate the increased opportunities to communicate and interact with young people and foreigners that resulted from the festival, which has brightened up their lives, even though improvements need to be made to the ways in which they communicate with foreigners.
7. It was revealed Okayama City does not provide significant support for the festival compared to Kagawa Prefecture. The local residents of Inujima, which is the only island that belongs to Okayama Prefecture, feel alienated because the festival is managed primarily by Kagawa Prefecture.
8. Local resident support for the festival is more passive than active. However, they are generally of the opinion that the festival should continue and understand that it is necessary to Inujima's continued existence as an inhabited island.

We found almost no disadvantages to the Setouchi Art Festival and that the local residents enjoy interactions with the young people and foreigners. The festival has not changed Inujima excessively, but we have learned that there are some things that would not have happened without it, and those things have added cheer to the lives of the elderly people that live on the island. As a result, it can be said that the festival has been successful up to now.

Acknowledgements

Our thanks go out to the Japan Society for the Promotion of Science (JSPS) for providing a Grant-in-Aid for Scientific Research (18K18602), and to the Obayashi Foundation. Additionally, our thanks are extended to the Inujima residents, the Setouchi Art Festival Committee, and the visitors who provided answers to our questions.

Invisible projects: imagined nearness as a tool to
explore long-term transitions of landscape/heritage.
The case of the river Tiber in Rome

Elisa Avellini¹

¹*Sapienza University of Rome, elisa.avellini@uniroma1.it*

Abstract: How to deal with landscapes (and heritage) whose transformation has only been imagined by built environment disciplines for more than a century? How can long-term transitions of landscapes/heritage be explored to better understand a territory? This paper focuses on invisible projects: imagined transformations that have been developed for the Tiber riverbanks, in the historic centre of the city of Rome. The “massive change” determined by the construction of the riverbanks, at the end of the Nineteenth century, is here taken as a starting point for a process of long-term transition for the landscape/heritage of the Tiber, in its relationship with Rome historic centre. Such a change has physically modified the perception of the river in the city, with the construction of two embankment walls along the river. Because of this change, planners and designers have had difficulties in rethinking a role for the Tiber riverbanks. This can be linked to a lack of effective analytical tools to address the (sometimes invisible) existing dynamics that occur in and towards the area. The concept of nearness will be introduced to investigate a number of narratives, representations and collective memories partaking on the construction of positions/points of view of who practices a place.

Keywords: landscape/heritage; long-term transitions; nearness; imaginary; Tiber.

Introduction

This paper aims to discuss possible ways to explore long-term transition of landscape/heritage in order to better understand transformation processes that are still continuing nowadays. This will be questioned through a case study whose long-term transition includes numerous transformation that have only been imagined by built environment disciplines for more than a century. I will focus on invisible projects: imagined transformations developed for the Tiber embankments, in the historical centre of the city of Rome.

The construction of the embankments of the river Tiber, in its section crossing the historical centre of the city of Rome, might seem to have determined an arrest in designing further transformations for it. Beginning from the early 1900's the river started its life across the city about 10 metres below the new urban level, leaving a physical gap with the rest of the city. The size of this transformation, that many have pointed as a terrible mistake for a synergetic development of the city with its river (D'Onofrio, 1970, Ravaglioli, 1982), seemed to have ended a possible further development, or at least a feasible further transformation.

Nevertheless, ideas, desires and aspirations (most of which impossible to put into practice) were not prevented from being produced, leading to a body of information regarding how such projects faced material and immaterial¹ obstacles to an actual transformation of the river embankments. This paper aims to discuss in which sense looking at projects apparently invisible, since never actually put into practice, can be of interest for built environment studies. The reasons for this are not to be found uniquely among analytical purposes: such a study can also lead to better understand transformation processes that are being carried on nowadays and possibly future processes too.

I will try to focus on these imagined transformations inquiring how material and immaterial dimensions have been integrated into these projects for the river embankments. In particular, I will introduce the concept of 'nearness' to investigate a number of narratives, representations and collective memories partaking on the construction of positions/points of view of who practices a place. This concept will be used as a tool to gather knowledge on how elements like representations and collective memories have been employed in an integrated way with more physical, visible aspects of a same place through time, as well as looking at how this integration has changed through time. Beginning from transformation proposals for the river elaborated between the end of the XIX century and the beginning of the 1900's, I will then look at some proposals from the 1960's and 1980's. I will then draw some conclusions on the concept of nearness for future uses.

A "massive change"

The current appearance of the riverfront running through Rome historical city centre was shaped, in its main features² following an exceptional flood occurred in December 1870, only a few months after the city was declared part of the Kingdom of Italy and subsequently capital city of Italy (Pasquali, Rossi, 1987). The first official discussions regarding urban transformations of the new-born capital happened to be about the future of the river in the city, so to respond to the effect of the recent flood. A specific commission was set to examine possible solutions to the river periodically flooding the city (ibid.). The commission focused on two directions of transformation: on one hand the construction of embankment walls high enough to prevent the river to flood, on the other hand options of deviations of the riverbed outside the city. This second option was eventually discarded by the commission, but it nonetheless produced several proposals, among which an idea fostered by Giuseppe Garibaldi, one of the main figures of the Italian unification. Starting from 1872, Garibaldi began to take an interest in the possible future structure of the Tiber, studying, unlike previous projects, a territorial scale solution that would have implied the reclamation of an extended area surrounding the city (Agro Romano). This project focused on the complete deviation of the Tiber and Aniene (its main tributary in the urban area) through a canal that would have crossed the areas east of Rome so to enter the Tiber again south of its urban area, as shown in figure 1. The urban stretch of the river would have been abandoned, with the intent to allow a small amount of water to flow through a complex hydraulic machines system (Pasquali, Rossi, 1987). This proposal imagined a parallel industrial development in the southern part of the city (ibid.) where it will be realized part of the few industrial interventions of the city.

¹ The terms material and immaterial are here understood according to a common sense meaning, for which material would be related to objects, constructions, buildings and, in short, what is tangible, while immaterial would be related to the history, memory, culture and social relations that meet in a particular place.

² Some elements of the current layout will be added later, like a riverside walk on both sides of the river in the 1950's (Insolera, 2011).

Figure 1. The course of the river as it was preserved (on the left) and the deviations of course of the river as they were imagined by one of Garibaldi's proposals (on the right). Drawing by the author

On that occasion, the construction of the embankment walls was preferred to the development of an industrial future, choosing to focus uniquely on the protection of the city from the river floods.

The approved project included, among others, the following points:

- the construction of 10 meters high walls along the banks;
- the definition of a constant width of the riverbed, fixed at 100 meters;
- the realization of two *lungotevere*, embankment streets at the new urban level (10 meters above the river);
- the construction of two collectors below the *lungotevere* that would have ensured the separation of the inland waters from those of the River (Ravaglioli, 1982).

Despite this, not even twenty years after this decision, a new scenario seemed to reopen for a possible industrial development. In fact, a new river port was planned, less than a kilometre northern the port of Ripetta, now covered by the construction of the embankment walls. This port already present in the Italian Geographic institute map of Roma of 1891 (Segarra Lagunes, 2004), was meant to be a part of a new industrial development, given the presence of a gasometer along the river and industrial settlements like a foundry and a tannery. This development was only for a short period part of the plans of the city: a few years later, the new urban regulations (1909) would have determined a residential end use for that area, leading to the demolition/dismissions of the industrial settlement to be replaced by a new neighbourhood (Flaminio) (ibid.). The river port nonetheless still remains, having though lost its purposes.

The physicality of the embankment walls did not stop, even during the XX century, the production of new urban imaginaries for alternative solutions. Between the 1960's and 1980's several projects were developed to offer

alternative visions to the material “gap” produced by the embankments³. Among others, two proposals (one by Paolo Portoghesi and Pierluigi Erolì and the other by Leonardo Benevolo) developed a plan addressing this issue, leading to extremely different conclusions.

The project by Portoghesi and Erolì is part of a collection of projects elaborated in individual and collective ways during their careers (Erolì and Portoghesi 1984). This collection produced through the years is meant to create a dialogue between the actual form of the city and “a second city. Conceived by the same architects of the first, made by their ideas, tensions, secret passions accumulated over time”. The purpose of this dialogue would be to “reduce the distance between these two cities” to “bring the world of aspirations closer to that of reality” (ibid.: 7, my translation). This collection aims to formulate a proposal to imagine a transformation strategy for the city of Rome. This strategy finds one of its main principles in the development of the Tiber into an “equipped” urban axis (figure 2). The banks of the river are imagined in most of the cases without the walls built in the Nineteenth Century so to give space to the “reconstruction” (ibid.) of buildings (for both residential and service/commercial use) along the banks, that are removed in order to proceed with the embankments. Removing the embankments was also meant to allow the resurface of parts of the city that were covered by the embankments, like the old river port of Ripetta, which in this project is reconstructed as it used to be.

Figure 2. The strategy along the river according to Erolì and Portoghesi (1984).

In 1977, Leonardo Benevolo proposed, within the book “Roma oggi”, a strategy of intervention for the historical centre of Rome, containing a specific strategy for the river. This consisted in the elaboration of a linear park that would have replaced the entire length of the embankments walls (figure 3). Such operation would have brought back on the surface not only the old river port of Ripetta, but also traces of the ancient Roman roads, now

³ For more design proposals addressing the river embankments see Muratore, 1983 and Purini et al, 1987.

hidden. The author describes this proposal as a “liberation” (Benevolo 1977) of the riverbanks, aiming to connect the city level with the river level through a long park for leisure activities.

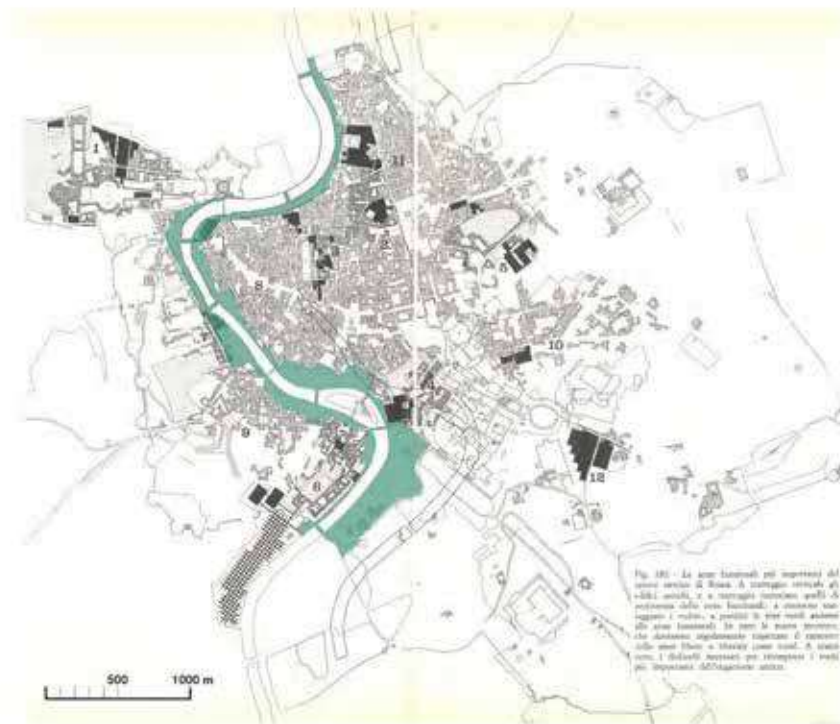

Figure 3. The strategy along the river according to Benevolo (1977).

Even though always trying to imagine alternative functions and roles for the river in the historical city, proposals have always struggled to balance the definition of new uses for the river with its historical and memorial value, leading to a reinforcement of the latter in the ways the future of the river has been thought. How can we better understand the relations underneath these proposals so to gain useful information for nowadays processes towards an actual (and not only imagined) transformation of the river? In the following section, a possible methodological tools will be discussed so to question what types of relations can be found between who have practiced the riverbanks in different ways (beginning from planners/designers who have tried during the last century to imagine a future transformation of the banks) and the place itself. The concept of nearness will be introduced to investigate a number of narratives, representations and collective memories partaking on the construction of positions/points of view of who practices a place.

Nearness

How are we “near” things or places? How the design proposals introduced in the previous section made emerge a relation with a place (the riverfront). Such relations cannot be limited to physical ones: the imagined solutions necessarily dealt, for instance, with historical and memorial issues. Through the idea of nearness, physical, material instances of the design proposals will be put in relation with immaterial, “invisible” aspects nevertheless present in those proposals. The concept of nearness will be here discussed through the work of Buchli (2010, 2013) on propinquity, Hall (1966) on proxemics and Low (2011, 2014, 2017) on embodiment and Altman and Low (1992) on place attachment.

The word nearness is used by Buchli (2010, 2013) to explain the ways a person or a group can feel attached to a place or thing. To explore this, he theorises the concept of propinquity (Buchli, 2010, 2013). This concerns not only a spatially referred nearness but a wider range of relationships with a specific place. Propinquity can be linked to nearness of personal relationships, of association, affinity, time, but it can also be related to narratives, stories (ibid.).

To understand the concept of nearness, it is useful to look at Edward T. Hall's (1966) concept of proxemics. This highlights the spatial distances people use according to different social relations. Analysing the distance receptors of our senses, being eyes, ears and nose (Hall, 1966, also quoted in Gehl 2011), Hall theorized four types of interpersonal distance: intimate (between 0 and 45 centimetres: the distance of personal feelings), personal (0,45 to 1,30 metres: the distance we use with close friends and family), social (1,30 to 3,75 metres: the distance we use for conversations with friends, colleagues, people we meet on the street) and public distance (over 3,75 metres: the distance for formal contexts) (Hall, 1966).

The concepts of embodiment, and embodied space⁴, (Low, 2011, 2014, 2017) and place attachment (Altman and Low, 1992) are also useful concepts to understand nearness. Embodiment, (ibid.) expresses "the location where human experience and consciousness take on material and spatial form" (Low, 2011: 467). The focus is centred on the actor, rather than on space: the actor's feeling, past experiences and thoughts are a means to give meaning to a place (ibid.). Place attachment (Altman and Low, 1992) underlines how place incorporates both individual and collective experiences and memories (ibid.). Place is not necessarily considered the final aim of attachment, but rather a mean that incorporates our experiences, with no distinction between the individual and the group (ibid.).

The word nearness has been chosen for its ambivalent stance between the physicality of place and its "intangibility", allowing to decline it as the set of knowledge, competences and resources on which the position of those who practice a place with respect of the same is constructed. It is therefore a feeling of appropriation and at the same time a proxemic of the individual towards a place. One's nearness to a place, therefore one's own position, also determines one's own point of view and, consequently, interpretation of a place, also generating the possibilities of use which have been imagined for it. This concept will be now put to the test on the case study of the river, as introduced in the previous section.

Invisible projects

In this section, the concept of nearness will be discussed through the analysis of two design proposals for the river, one by Eroli and Portoghesi (1984) and one by Benevolo (1977) previously introduced. In both cases, the focus will be drawn on the specific proposals for the area surrounding the Ripetta river port, covered by the embankment walls. The analysis will underline the main elements of the proposals in relations to the uses that these imagined transformations would have brought and some of the immaterial qualities that have fostered those material changes. This will help to understand a network of relations, "nearness", some tighter than others, representing the positions one could have, according to the proposals, towards material and immaterial qualities of the place.

Eroli and Portoghesi's proposal focuses on five main elements: the first is the Tiber river; the second is obviously the port of Ripetta, which is rebuilt since its archaeology; the third element that we can identify are the boats, which in the intentions of the designer should cross the river making base on the renewed port; the fourth element is the construction of dwellings and services conceived by the authors to replace the current

⁴ Low explains that "the body (bodies), conceptualized as embodied space(s), incorporates metaphors, ideology, and language, as well as behaviours, habits, skills, and spatial orientation derived from global discourses and faraway places [...] and yet is grounded at any one moment in an urban location" (Low, 2011: 464).

embankment walls; the fifth element is finally constituted by the same embankment walls, which are partially kept to constitute the boundary and the visual horizon of the area drawn in the view (figure 4).

Figure 4. The reconstruction of the Ripetta river port (Eroli and Portoghesi, 1984).

Through a nostalgic reconstruction of the river port of Ripetta this element is reconnected to the hypothesis of commercial and leisure uses, as the presence of boats also. The dwellings along the river have the clear purpose to be inhabited and to provide services to the surrounding areas. The walls on the other side, seems to remain the visual horizon of this scene, without however seeming connected by any kind of use to the river or other spatial elements present. Looking at the uses related to each of these spatial elements, we can then try to imagine what immaterial qualities, according to the proposals, should have been connected or incorporated to the various elements.

In the description of the whole "renovatio urbis" operation (Eroli and Portoghesi, 1984), the two authors make a broad and clear reference to memorial issues, to the (re)foundational meaning of the place constituted by the restoration of a precise ancient monument or archaeological finding, that is the port of Ripetta. The latter therefore seems clearly to be distinguished by the ability to evoke an evenemential history, that is the city's past, but also to evoke collective memories of a past that, even at the time of the proposal, was not so recent but still deeply present in narratives of the relationship between the Tiber and the city. These capacities to evoke the history and memory of the place held by the port are shared with the river, which is an integral part of this narrative. To some extent, also the walls play a role in this process, playing, according to the authors, the "negative" role of having erased testimonies of how life along the river used to be (ibid.).

Collective memory of citizens is also embodied in these elements in different ways: if the river and the walls share the same memorial experiences and a common narrative, the port is only tangentially linked to them, as a "spectre" (de Certeau, 2001) of something that was no longer there and which must be recalled nostalgically.

The port and the boats are clearly connected by the idea of a possible exchange, mainly in a commercial sense but also in a broader sense of movement, while an idea of everyday life seems to unite the buildings on the river with the boats, which would share a same routinary "landscape" of use, even though they would not necessarily be connected otherwise. At this point, it is possible to understand the positions, both physical and ideal, that the individual could occupy within this so designed place, observing then that degrees of nearness the place would have offered him/her, who would then have to re-elaborate them based on his/her personal experience. The project seems almost divided into two blocks, with history, memory and nostalgic practices to have a preeminent part and struggling to integrate the physicality of buildings that are only a form landscape, having little effect on everyday experiences.

As the second proposal is concerned, the key element underlined by Benevolo (1977) is the idea of a linear park on both sides of the river, to replace the embankment walls. The main elements of this project are: first of all, the spatial element constituted by the park; secondly, the embankment walls themselves, paradoxically present in this proposal through their absence; an additional element can be identified in the port of Ripetta, which is also restored in this intervention; finally, the traces of ancient paths, also made reemerged as the river port.

The relationship with the walls becomes clearly non-existent given the disappearance of the latter in favor of the birth of the linear park, with which instead comes to constitute a connection through uses related to leisure. The same type of use related to free time and a nostalgic re-enactment connects the river with the ancient paths and with the port. The immaterial qualities to which these elements seem to be related are primarily aspects evoked by leisure: ideas of everyday life but also of affectivity towards a long river park that seems conceived to create a special experience in the everyday lives of the Romans. If the port is once again evoking ideas of exchange, it is the history and collective memory of place to have a prominent role, through the reconstruction of streets and ancient monuments, but also through the disappearance of the embankment walls that remain part of a memorial narrative of the place (and with its disappearance it becomes part of its past).

The history of Rome is proven once again to be one of the strongest traits uniting most of the spatial element of the proposal, building a symbolic link between the river, the port and the reemerged ancient paths. Tangentially, also the embankment walls are part of this relation, entering to be a part of the past, even if a less ancient past and, in a certain sense, less (rhetorically) prestigious. As mentioned earlier, great importance is given to the construction of a park which builds a strong connection with the river in terms of naturality, as well as in terms of daily use and no longer in terms of exceptional use. The work on the historical qualities of the place tries to connect with an attempt to build a daily atmosphere of use, defining a nearness to the place that is based on the combination of daily experience and historical re-enactment.

Conclusion

After a closer look to these "invisible projects", it is interesting to point out how they are not only design proposals remained on paper, but they are also part of processes that through the concept of nearness can be unveiled. Nearness is then a tool not only to analyse the qualities of those never realised projects, but also to underline ongoing processes that architectural and urban design are not able to grasp, like "involuntary" design processes that have a long-term development.

In the case of the river Tiber, the concept of nearness can be useful to highlight a predominant point of view that have been adopted (in more or less voluntary ways) to look at the river, especially the part crossing the historical centre of the city, which sees it "only" as a monument, symbolically and socially important, but almost impossible to "dwell". In order to think of a future for the river, it will be necessary to find a compromise between its monumental state and the declared necessity to use it, to inhabit it and stay close to it. In this sense, the concept of nearness is not meant to be only a tool for retroactive analysis, but also a tool to be put at work in contemporary and future designs.

Track 1: Transforming built heritage and landscapes

Assessing the Transition From Traditional To Participatory Heritage Management In Turkey

Gizem Aydin*¹, Clarice Bleil De Souza¹, Federico Cerutti²

¹ *Welsh School of Architecture, Cardiff University*

² *School of Computer Science and Informatics, Cardiff University*

**ayding@cardiff.ac.uk*

Abstract: Turkey is in a unique geographical position with 18 nominated World Heritage Sites. Since 2005, United Nations Educational, Scientific, and Cultural Organization (UNESCO) World Heritage Committee requires a management system through participatory means to guarantee the protection of these sites. In this same year, Turkey enacted the associated legislation by proposing a new actor named *site manager* who has both local and professional knowledge with the main role of coordination of the site management system to ensure protection of the nominated property through participation. Public participation is therefore mandatory in the site management processes in Turkey. The aim of this research is to examine current site management practices in Turkey to understand how they address public participation inferring how the site manager scrutinises public participation during the development of the management plan. A combination of qualitative analyses is proposed to assess information contained in the documentation available for the development of management plans, including the management plans themselves. The focus is on understanding how knowledge from public participation is transferred, from focus group meetings to management plans, considering the actors, actions and outputs involved in the process. This case-based proof of concept provides a set of indicators to model public participation in site management processes to resolve the mistrust issues between authorities and communities and to gauge the level of knowledge transfer by the *site manager*.

Keywords: heritage management, community involvement, participation, knowledge engineering, comparative analysis

Introduction and background

The idea of public participation as a political principle has been part of several agendas for sustainable and economic development. The “Local Agenda 21” (UNCED, 1992) introduced the concept of “capacity building” to widen public participation from national to local government levels. The United Nations Economic Commission for Europe (UNECE) signed a convention with 46 members states in 1998 emphasizing three pillars to promote a healthy environment and securing citizens’ rights based on: access to information, public participation in decision-making and access to justice (Aarhus Convention, 1998). Few years later, the Organization for Economic Co-operation and Development (OECD, 2001) published the handbook on strengthening the relationships between citizens and governments.

Theories and methods related to public participation in urban planning can be found in the works of Arnstein, 1969; Cole, 1974; Davidoff, 1965; Davidson, 1998; Fainstein, 2000; Fischer, 2000; Forester, 1999; Friedmann, 1965; Healey, 1997; Innes & Booher, 2004; Innes, 1996; Sanoff, 2000, to cite a few. Davidoff (1965) pioneered in bringing public participation to urban planning agendas through the idea of advocacy planning. In subsequent

years a series of theories started being developed such as Transactive Planning (Friedmann, 1973), Equity Planning (Krumholz, 1982), Consensus Building (Innes, 1996), Collaborative Planning (Healey, 1997), Cosmopolis (Sandercock, 1998) and the Just City (Fainstein, 2000). The aim behind all these theories was primarily to bridge the communication gap between the public and planning professionals.

In parallel with these theories, there were studies which addressed public participation from a more practical and empirical perspective such as the work of Arnstein (1969) and Davidson (1998). These studies examined the engagement level of public authorities with communities. Arnstein's (1969) model Ladder of Participation was developed to categorize different types of community involvement, from non-participation to citizen empowerment, after assessing the Model Cities program implemented in the USA in 1966. Davidson (1998) reinterpreted Arnstein's model critiquing the idea of levels and replacing it by the Wheel of Participation model which advocated the concept of a non-linear spectrum of participation between government and communities. Gibson (1986) focused on residents' real needs and preferences and raised the Planning for Real method to overcome the communication gap between planners and residents. Glass (1979) created a matrix of objectives and techniques of participation, while Lane (2005) analysed the relationship between planning theories and public participation.

Nowadays the literature in this domain is copious. The realm of public participation is defined, theorized and practiced by its elements, limits, tools, and methods in many areas. However, most of the work related to it still focuses on the processes of engagement between citizens and communities with public authorities assuming that information and knowledge transfer depend primarily upon it. To the best of the authors' knowledge, there are no records in the literature related to the assessment of how successful knowledge from citizens and communities are effectively translated into planning actions i.e. there are no methods to test how much information from community engagement is actually used in the development and implementation of planning decisions to judge if participation is actually happening or if it is merely a paper exercise.

This work proposes to start a discussion in this important aspect of public participation. It focuses on understanding public participation in conservation, tracing how knowledge from public participation is transferred from focus group meetings to management plans considering the actors, actions and outputs involved in the process. The method is illustrated as a proof of concept through a case study in Turkey and provides a set of indicators to model public participation in site management processes in conservation of heritage sites to resolve mistrust issues between authorities and communities and to gauge the level of knowledge transfer by the *site manager*.

Participation in site management plans in Turkey

Management plans are a required document to apply for nomination for UNESCO World Heritage Site since 1994. These documents specify the management system of the heritage site and the way of preservation of its "outstanding universal value" (UNESCO, 2008, IIF.108). They are regulated by an administrative organizational and operational structure and legalise actions to implement management systems in these heritage sites. Since 2005, they impose management system through participatory means "to ensure the effective protection of the nominated propert[ies] for present and future generations" (UNESCO, 2005, IIF.108) requiring countries wishing to apply for UNESCO nominations to adapt their own national legislation and regulatory framework to comply with it.

Turkey incorporates site management plans as defined by UNESCO to its legislation in 2004, by Law no. 5226 making changes in Law on Conservation of Cultural and Natural Assets and Other Laws. This change in law states site management plans as mandatory and defines as "conservation and development projects defined with yearly and five yearly implementation phases and five yearly review plans, generated by considering the management plan, excavation plan and if any, landscape plan or conservation master plan in order to protect, sustain, valuate of the related site management area." (Law no. 5226, 2004, Article 1(11)). In 2005, the

regulation for the Substance and Procedures of the Establishment and Duties of the Site Management and the Monument Council and Identification of Management Sites becomes effective. Those legal amendments include a mandatory protocol for public participation to become an integral part of site management processes as required by UNESCO. The role of the site manager is then defined in the regulation as the actor who:

“has previously worked on the area, has adequate knowledge of the area, can develop a specific vision for the area, has knowledge on new approaches to cultural and natural property management, is experienced in management policies and implementations, is a graduate from university departments such as architecture, urban and regional planning, archaeology, art history, public administration, business management and economics shall be appointed by the relevant municipality to manage the urban conservation sites and shall be appointed by the Ministry to manage non-urban conservation sites.” (Regulation for Site Management, 2005, 3(14))

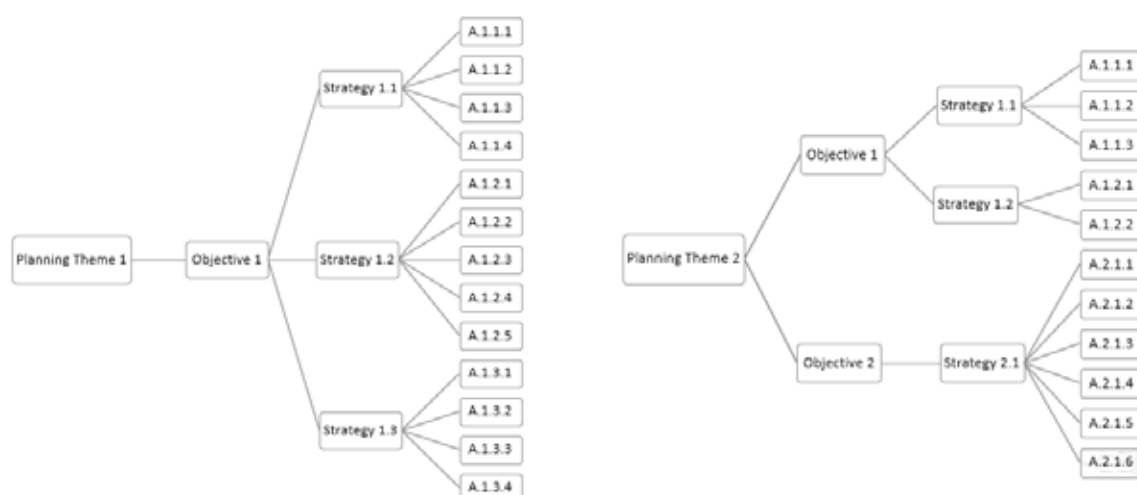

The site manager is supposed to act as a catalyst for the transition from traditional to participatory heritage management once in charge of coordinating the development and implementation of a management plan. However, can this actor coordinate the interpretation and transferring of knowledge gathered from public participation into actions? Do those actions address the problems of the place and enhance its values? How are the different community actors and stakeholders involved in the development and implementation of the actions and outputs defined in the management plan?

The proposed method

Two types of documents were investigated in detail: (i) Reports from focus group meetings and (ii) Site management plan. The former, being the most important record of community participation in the heritage management process, summarises a set of issues raised by the different stakeholders involved in the project, expressing insiders' knowledge of the site and its context. The latter, is the official document, prepared by a project team coordinated by the site manager and contains, in theory, community knowledge embedded in it as it is prepared based on a SWOT analysis which merges a technical assessment of the site with information coming from focus groups.

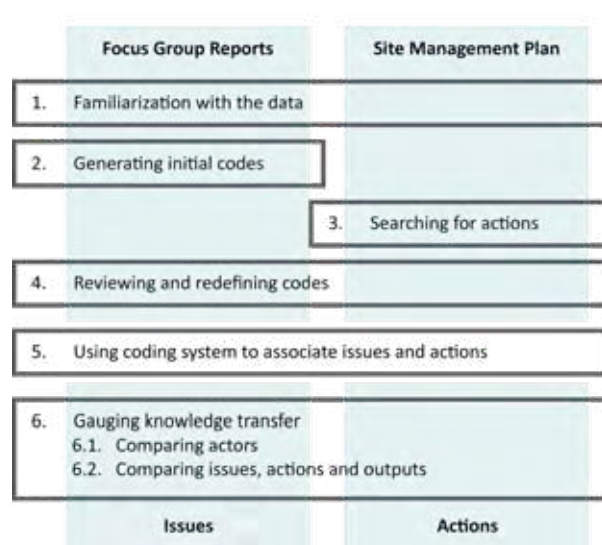

Focus group reports are structured according to a set of themes derived from focus group meetings whereas management plan content is structured according to Figure 1. Each planning theme has a set of objectives, which have a set of strategies with a subsequent set of related actions structuring guidelines for the implementation and monitoring of the management plan.

Figure 1: Management Plan Structure

A content based thematic analysis was undertaken to extract patterns of knowledge transfer (Braun & Clarke, 2006). The first stage of this analysis comprised familiarization with the documents to understand the types of discussions happening in focus group meetings and the types of actions defined in the management plan. Initially, recurrent issues or patterns of issues were extracted from focus group reports for the different geographic locations within the boundaries of the heritage site, generating an initial coding system¹ around which different stakeholders could be grouped. Stakeholders involved in the different focus group meetings were then associated, according to the different issues they raised, to this initially generated coding system. This coding system was used to search for actions in the management plan which would, in theory, respond to issues raised by the different stakeholders. However, this association was not linear and involved a series of iterations between searching and re-coding, until a final coding system was produced (Figure 2).

Figure 2: Methodology Diagram

Associating actions in the management plan with issues raised by interactions with all stakeholders involved in focus group meeting was the first step to assess knowledge transfer from community participation to management plan implementation. This association enables one to gauge, at least qualitatively, how much issues raised by the community are translated into actions in the management plan. Qualitative gauging is defined at three different levels: (i) Actions which are a direct translation from issues raised by different stakeholders, (ii) Actions which are partially or indirectly translated from issues raised by different stakeholders and (iii) Absence of actions to address issues raised by different stakeholders. This gauging is undertaken for the actions which are directly, indirectly or partially translated from issues raised by stakeholders according to the following types of assessment:

- Verifying whether stakeholders from focus group meetings are transformed into actors responsible for implementing the action, beneficiaries of the action or consultants on the action being implemented;
- Verifying if there is a designated budget for the action;

¹ Coding system in Social Science means essentially labelling recurring themes in a data source

- Discussing if an issue raised in the focus group report is translated into an action reported in the management plan considering the corresponding outputs used to monitor its success.

Knowledge is considered transferred when there is correspondence between community stakeholders from focus groups and implementers, beneficiaries and/or consultants in the management plan. An action is considered implemented if a budget is allocated to it. When they mitigate issues, actions' outputs are compared to ideal scenarios to monitor their implementation.

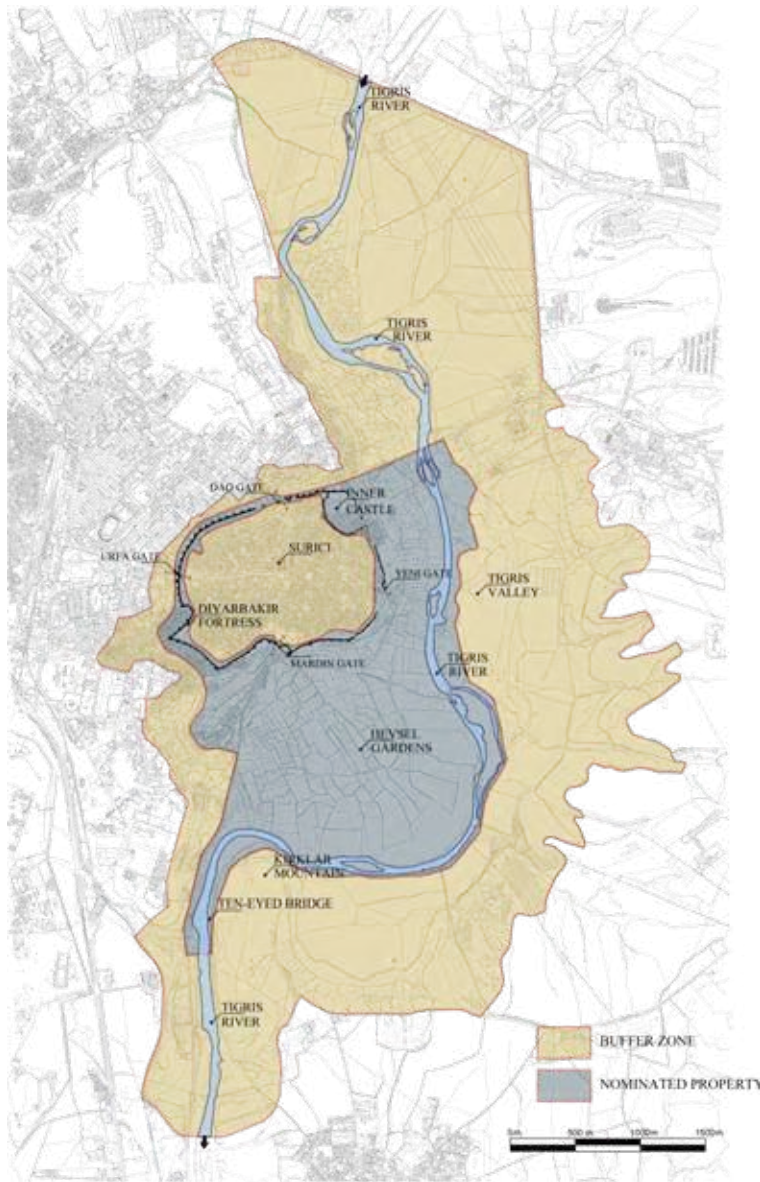

The method is applied to the case of Diyarbakir Fortress and Hevsel Gardens Cultural Landscape which is inscribed by UNESCO World Heritage Committee as a world heritage site in July, 2015 (Decision: 39 COM 8B.32, 2015). In 2000, the site was included in the temporary nomination list of UNESCO World Heritage List (WHL). Diyarbakir Greater Municipality started the process of the preparation of site management plan and UNESCO WHL application dossier in January, 2012. The site management plan was completed in November, 2013 and official nomination dossier was presented to UNESCO WHL in February, 2014.

The Diyarbakir Fortress and Hevsel Gardens Cultural Landscape

The site is located in the city of Diyarbakir, in South-eastern Anatolia Region of Turkey and includes a fortified city with its adjacent and surrounding landscape. The city walls are the longest ones in the world after the Great Wall of China and were constantly modified throughout the Hellenistic, Roman, Sassanid, Byzantine, Islamic and Ottoman periods as the city was a regional capital. The Tigris River and the Hevsel Gardens supply food and water for the area, hence being site and cultural landscape due to their outstanding universal value, respectively defined as *works of man* and *combined works of nature and man* in the UNESCO World Heritage Convention (UNESCO, n.d. Article 1). The nominated property with its 7000 years history has six components: Amida Mound, City Walls, Hevsel Gardens, Ten-Eyed Bridge, Tigris Valley and natural resources (Figure 3).

The Amida Mound is an archaeological area known as inner castle and located on the northwest of the fortress, built on the Fiskaya cliff with 4 gates and 19 bastions (Figure 3). The city walls are 2 meters wide, comprise 82 bastions, and extend through 5.8 km once the inner castle is included. Bastions are built in three or four storey with the first two enclosed and used for storage or military purposes. Upper levels are built as terraces and have a wider surface area. The city walls have four gates opening to north, south, west and east (Figure 3). Hevsel Gardens are both agricultural lands as a source of livestock and cultural landscape, combined works of nature and man as defined by UNESCO. They are located in the southeast of the fortress and cover an area of 400 hectares. Ten-Eyed bridge is on the southern border of the property and its name comes from its ten arches.

Ten-Eyed Bridge (Tuncay Cilasun 2019)

As inscribed in the UNESCO WHL, this heritage site has a management plan, which was informed by community involvement through participatory meetings, cf. Article 108 of (UNESCO, 2005). Records of community meetings are documented in focus group reports and the resulting management plan should in theory reflect the interests, ideas, problems and needs of the people who have a stake on the heritage site. Both documents will be used as a basis to illustrate a proof of concept of the proposed method to assess community knowledge transfer throughout the planning process.

Proof of concept and discussion

Community engagement took the form of: (i) Focus group meetings and (ii) Search workshops to inform the SWOT analysis.

The project team conducted eight focus group meetings to list and discuss current issues and needs of the heritage site according to the viewpoint of its different stakeholders. Each focus group had clear theme and a predefined area of common interest to all stakeholders taking part on the meeting. One can infer three different criteria used to organise focus group meeting: (i) Documentation and management of heritage and tourism, (ii) Management of urban and agricultural land use and (iii) Special needs of specific groups of people. Table 1 shows an extract of areas of interest and the participants involved in each of these eight focused groups. Participants included a comprehensive list of stakeholders: public authorities (municipalities, etc.), NGOs, development agencies, universities and, different types of chambers, associations and foundations. A summary of the discussion which happened in each of these eight meetings is documented in a single report.

Besides focus group meetings, the project team also organised two search workshops for the heritage site focused on Hevsel Gardens Cultural Landscape and Diyarbakir Fortress with Surici Area. These workshops were designed to inform a SWOT analysis used in the development of the management plan. Outcomes of it are presented in the management plan as a single summary table which does not form part of this analysis as it lacks detail and information related to different stakeholder participation.

Table 1: Focus Group participants and area of interests

Focus Group and its acronym	Area of interest	Participants of the meeting
HM Heritage Management and Tourism	Institutional structure of the heritage management based on its preservation, economic development, and institutional capacity of competent authorities	. Diyarbakir Provincial Directorate of Culture and Tourism . Diyarbakir Cultural Values Conservation Committee . Diyarbakir Greater Municipality Site Management Unit . Museum of Diyarbakir . City Planners Chamber . Landscape Architects Chamber . Architects Chamber . Yenisehir Municipality . Karacadag Development Agency . Diyarbakir Greater Municipality Coach Station . Special Provincial Administration
SM Spatial Management	Spatial structure of the area, urbanisation, conservation, infrastructure and built environment quality of the heritage area and its surrounding	. Diyarbakir Provincial Directorate of Urbanism and Environment . Diyarbakir Provincial Directorate of Culture and Tourism . Diyarbakir Cultural Values Conservation Committee . Diyarbakir Greater Municipality Site Management Unit . Museum of Diyarbakir . City Planners Chamber . Architects Chamber . Sur Municipality . Yenisehir Municipality
HG Hevsel Gardens	Agricultural structure of Hevsel Gardens, its management, production and marketing problems, importance of agriculture for local communities	. Farmers . University representatives . Sarmasik Association . Professionals Association . Agriculture General Directorate . Diyarbakir Greater Municipality Infrastructure Department . Diyarbakir Greater Municipality Public Health Department

Greater Municipality of Diyarbakir Social Services Directorate . Disabled Branch / Local Agenda 21 . Visually Impaired Sports School Association

The familiarization stage involved a detailed reading of the focus group reports and management plan. Information was extracted from the issues found in the focus group meetings for the two different types of predominant land uses of this heritage site: Urban land-use in Diyarbakir Fortress and Surici area and agricultural land-use and natural landscape in Hevsel Gardens and Tigris Valley. Common issues related to the heritage site as a whole, its management and coordination between different types of land uses were also identified. The management plan was used to review and refine the information extraction strategy so issues and actions could be associated and qualitatively gauged against each other.

An example of the information extraction strategy for this case study is displayed in Table 2 which presents the geographic location in which the issue arises with a brief description of what the problem is followed by the code attributed to it. For consistency purposes, codes were kept identical when a similar type of issue is raised in different geographic locations. Table 2 illustrates for instance that issues related to coordination can happen in the urban area, rural area or over the heritage site however differences arise in relation to what is being coordinated and therefore who is involved in this coordination. A total of 41 entries were produced for this case study, 20 are attributed to Diyarbakir Fortress and Surici Area; 14 are attributed to Hevsel Gardens and Tigris Valley and 7 are attributed to the heritage site as a whole.

Table 2: Illustrating the information extraction strategy: each row in the table is an entry

Geographic location: Diyarbakir Fortress and Surici Area Issue description: Due to the increasing obscurity in Surici, there is an urgent need of coordination among institutions and NGOs. Code Label: Coordination
Geographic Location: Hevsel Gardens and Tigris Valley Issue description: Due to the large number of authorised institutions in the area, different projects planned by different authorities without coordination and this damage the natural structure of Hevsel Gardens and Tigris Valley. Coordination between authorities should be provided to solve the pollution and production problems. Code Label: Coordination
Geographic location: The Heritage Site as a whole Issue description: Lack of coordination between institutions cause to fragmentary and unreliable documentation of intangible cultural heritage. Only through coordination, the multi identity of heritage can be maintained. Code Label: Coordination

An example of the association of actions and issues is presented in Table 3. This case study has a total of 242 actions, from which 207 of them somehow relate to focus group meetings. The 35 actions not related to information coming from focus group meetings mainly refer to the preservation of tangible and intangible cultural values, improvement in the quality of life, and tourism activities with the respective spatial organizations related to it. Four of these actions are expanded to illustrate the analysis process in detail. The first two actions are related to the need to increase the number of food markets in the Surici area whereas the third and fourth refer to universal spatial accessibility in public spaces and historic sites. These issues illustrate special needs of specific groups of people who participated in focus group meetings, providing iconic examples of community knowledge inputs to the participatory process.

The purpose of associating issues with actions is to analyse how the first informed the latter; i.e. to analyse how issues in focus group meetings were, in theory, used to inform actions in the management plan. This analysis comprises examining whether stakeholders from focus group meetings are beneficiaries, implementers and/or act as consultants for the actions listed in the management plan (Table 4). The analysis is complemented by examining how each issue, as reported in the focus group meeting, is translated or re-written in the form of an action in the management plan including the corresponding output used to monitor its success (Table 5).

Table 4: Verifying stakeholders' involvement in focus group meeting and management plan

Action	Community Stakeholders from focus group	Beneficiaries	Consultants	Implementers
PT2 - S 1.2: Action 1.2.1: Reviewing the Suriçi market structure to conduct food demand forecasts in neighbourhood scale and increase the number of food stalls and market clusters	W <u>Consumers:</u> AÇEV – Mother Children Education Foundation; ÇATOM – Multi-purpose Commercial Centre; Ceren Women Association; Woman Branch / Local Agenda 21; Sarmasik Association; Woman Education Mental Health Consultancy Service Centre	Hevsel Gardens producers, Consumers Budget: ~88.359 EUR (580.000 TRY)	Tigris University Faculty of Agriculture; Agricultural Engineers Chamber; Diyarbakır Greater Municipality Information Technology Directorate; South-eastern Anatolia Project Regional Development Administration; Diyarbakır Chamber of Commerce and Industry; Diyarbakır Chamber of Agriculture	Diyarbakır Greater Municipality Resource Development Directorate; Diyarbakır Provincial Directorate of Food Agriculture and Livestock

Table 5: Issue from focus group with corresponding action and output

Issue	Action	Output
<p>Food market</p> <p>The prices in the food markets are reasonable because they supply vegetables and fruits from Hevsel Gardens.</p> <p>Local people request to increase the number of food stalls and market clusters.</p>	PT2 - S 1.2: Action 1.2.1: Reviewing the Suriçi market structure to conduct food demand forecasts in neighbourhood scale and increase the number of food stalls and market clusters in the area	Analysis reports showing food demand predictions; Number of market places established based on these reports
	PT2 - S 1.2: Action 1.2.2: Developing an organizational structure that can monitor the food prices in an effective and dynamic way and stabilise the market rate	Establishment of the organizational structure that can stabilise the market rate; The number of experts who monitor the food prices as a part of this organizational structure
<p>Accessibility</p> <p>The occupation of streets by commercial activities make women feel unsafe and uncomfortable to walk in the streets.</p> <p>Bastions and city walls should be accessible to disabled people. At least, the most important ones.</p>	PT3 - Action 6.1.3: Conducting spatial arrangements to make public spaces handicap-friendly and transforming public spaces to areas that can be easily used by women, disabled and disadvantaged groups	Number of public spaces that have become disabled friendly; Length of the pedestrian walkway on which tracking bricks are laid; Number of traffic lights with sound warning system; Number of disadvantageous groups that use public spaces
	PT5 - S 6.1: Action 6.1.6: Creating a safe and accessible structured environment for the elderly, the handicapped and the children	The number of interventions undertaken for the elderly, disabled and children on bus roads, stops, ramps, traffic lights and pedestrian walkways

Table 3, illustrates that issues related to food market are raised by one focus group only, the one related to the special needs of women in the area. However, Table 4 shows that women related NGOs are not clearly represented in either of these actions. Beneficiaries are only listed for Action 1.2.1 and stated as generically the ones trading and consuming in these markets. Interestingly, Hevsel Garden producers, despite being direct beneficiaries are not included as either implementers or consultants to this action. From Table 2, one can infer

their interest might be represented through consultants from professional association which attended the Hevsel Garden focus group meeting, but there is no documentary evidence for this. As a whole, in both of these actions, there is no documentary evidence of contact between implementers and the community. Implementers of Action 1.2.1 are mainly the greater municipality and the provincial directorate, which did not take part on the women or Hevsel Garden focus group meetings.

When looking at Table 5, it is possible to see that the community claims prices are reasonable and therefore should be maintained. This request is directly translated into the proposal of a regulatory structure to control food prices with outputs which, in spite not directly measuring this implementation and not having a designated budget assigned to it, seem to suggest it will be provided. The action and its outputs might attend consumer requests but no evidence is provided in relation to how producers will take part in this decision-making process, making it a potential focus for community tensions.

Table 5 also illustrates the community requests to increase the number of food stalls and market clusters. This action is translated into an assessment, comprising a review of current market infrastructure followed by a forecast on demand with outputs dependent on results from this analysis. Outputs however, are mainly quantitative, i.e. they relate to demand predictions with numbers of places established based on them. There is no documentary evidence in relation to the placement and positioning of these new food stalls and market clusters in space as well as no documentary evidence in relation to how the community will have a say on these and will be taken into consideration in demand assessments.

Table 3 illustrates that issues related to accessibility are raised by four different focus groups. Two of them contain community representatives from women in the area and people with disabilities whereas the other two contain representatives of heritage management and tourism as well as representatives of urban land use management. For the purpose of illustrating the community role in relation to this issue, only community focus group stakeholders are listed in Table 4. No target groups are specified for these actions and community representatives are supposed to be part of the list of consultants as 'relevant NGOs' in Action 6.1.3. One can infer that community interests might be represented by the Diyarbakır Greater Municipality Social Services Directorate, an implementer of Action 6.1.3, which attended the focus group discussion for people with disability but there is no direct community involvement other than through this municipality actor. Implementers in this case are mainly the Diyarbakır Greater Municipality departments while other municipalities are acting as consultants.

Issues raised by the community, as reported in Table 5, mainly refer to conflict of use in the urban space, lack of universal accessibility to heritage monuments and problems related to pedestrian vehicle segregation. Action 6.1.3 relates to the implementation of principles of universal accessibility to public spaces, whereas Action 6.1.6 refers to general improvements in accessibility for children, the elderly and people with disabilities despite no budget being assigned to it. Outputs are unspecific in relation to the types of solutions proposed with the exception of traffic light systems, ramps and pavement. They are also purely quantitative, i.e. not referring to any specific areas to be transformed, not even heritage monuments despite them being clearly listed in issues coming from focus group meetings.

As a whole, the four actions examined enable one to conclude that there is a weak involvement of the community in this part of the decision-making process. Despite initial consultation, members of the community are partially listed explicitly as beneficiaries and also partially or indirectly involved as consultants to the actions proposed. Actions' outputs are mainly quantitative, i.e. with no specific site location for them to be implemented, despite community clarity in this respect. The lack of budget for two of the actions (Action 1.2.2 and Action 6.1.6) examined suggest their implementation is no more than a paper exercise, especially considering they have clear costs associated to the proposed outputs.

Conclusion and future work

This paper proposed a method to assess and understand how knowledge from public participation is transferred from focus group meetings to management plan considering the actors, actions and outputs involved in the process. A proof of concept of the method is demonstrated through the assessment of parts of the UNESCO WHL application dossier for the Diyarbakir Fortress and Hevsel Gardens Cultural Landscape in Turkey. This proof of concept is supposed to be the starting point in the development of a method to test how much information from community engagement is used in the development and implementation of planning decisions to judge if participation is actually happening or if it is merely a paper exercise.

By extracting and relating some of the information in reports from focus group meetings with the some of the information contained in the management plan available for this area, it was possible to start assessing the level of control and influence communities had in relation to the implementation of the different actions proposed in this plan. It was also possible to see how communities would benefit from the implementation of the different proposed actions and to what extent the outputs proposed for these actions would better integrate communities to the related world heritage site.

The assessment was qualitative and undertaken for only part of this case study. However, the method has proven already useful as it could clearly identify different degrees of community involvement in the decision-making process as well as gauge how actions proposed in the management plan could benefit them. The method will be used to assess the 207 actions of this case study and also applied to two other UNESCO World Heritage Sites in Turkey in future studies. Through that, the authors expect to develop a set of recommendations for declaring community involvement more effectively in management plans and better translating issues raised by them into a set of actions with outputs that are not only measurable but also more clearly related to the effective protection of the nominated sites. Work in this area can contribute to the development of new guidelines which can empower UNESCO to check the effectiveness of public participation in WHL applications.

Besides that, assessing knowledge transfer, in general, is important in reinforcing the need to maintain community participation throughout site management processes. However, further studies are needed to enable the identification of patterns and types of actions to produce a proper theory generic enough to assess knowledge transfer in different types of participatory projects. For instance, clarity is needed in relation to which pieces of information need to be extracted from reports of community meetings and management plans to prove or disprove community engagement.

Transitions towards landscape- and heritage-centred local development strategies: A Multi-Level Perspective

Angela Barbanente¹, Laura Grassini²

Abstract: At the beginning of the new century, the European Landscape Convention (ELC) marked a paradigm shift in the conception of landscape, which is now conceived of as a common good and of crucial importance to people's everyday lives. A challenge is thus to find new approaches and tools to make the new concept translated into practice. The paper employs the Multi Level Perspective (MLP) to analyse transition pathways towards innovative forms of landscape management. In contrast with a linear conception of innovation, the use of this framework enables the authors to show nested and bi-directional dynamics of change across multiple levels and the interactions between different sectors/actors: governance and policy, professionals and public administration, grassroots organizations, citizens, market, industry. The paper focuses on the way new concepts and tools for landscape protection and improvement have been spread into planning practice in the Apulia region through the development of the new Territorial Landscape Plan (TLP). In the analysis, a particular attention is paid to the way innovative forms of management of landscape are actually mobilized, supported and given long-term perspectives, while resistance to change is lowered throughout the development and the implementation of the plan.

Keywords: transition, spatial planning system, landscape, heritage, multi-level perspective

Introduction

The European Landscape Convention (ELC), signed in Florence in 2000, marks a turning point in the way landscapes are or should be regarded by decision-makers, professionals, academics, and the people at large. The general aims of the ELC are to promote European landscape protection, management and planning as a key element of individual and social well-being. Among other things, it requires a crucial shift from an exclusive focus on the identification, valorisation and protection of 'special' landscapes towards the acknowledgement of the importance of the qualities of the ordinary, the everyday, even the degraded or stigmatized places. According to the ELC, landscape "is an important part of the quality of life for people everywhere: in urban areas and in the countryside, in degraded areas as well as in areas of high quality, in areas recognised as being of outstanding beauty as well as everyday areas" (Council of Europe, 2000, Preamble).

This implies the need of a radical change from the way landscape planning practices have been developed across Europe and in Italy in particular, where heritage and landscape issues have been traditionally tackled through the development of ad-hoc legislation, which imposed the statutory protection of places of exceptional beauty. In Italy the first law of this type was passed in 1939, then followed by the so-called Galasso law in 1985, which enlarged

the range of areas to be protected by law to environmental features, while keeping the same approach to protection through binding rules and regulatory plans. These plans were mostly sectorial and focused on single protected areas, i.e. extra-urban areas of ‘extraordinary beauty’ or high environmental value, detached from the complex and conflictual transformations of the territory.

The elitist conception of landscape and the regulatory focus of plans nevertheless proved to be largely ineffective to contrast widespread practices of landscape disruption, as strategies for economic growth and local development kept being made without any consideration for landscape and heritage. Laws and rules for landscape protection as well as any plan trying to enforce them were largely regarded as constraints that might limit pro-growth interventions, thus poorly tolerated or opposed by local governments and communities. This happened despite in most cases pro-growth plans not only betrayed the promised solutions to economic and social problems, but also produced huge environmental and territorial damages.

Partly in line with the innovations introduced by the ELC, the new Italian Cultural Heritage and Landscape Code (2004, amended in 2006 and 2008) combines some innovations of the ELC with the Italian legal system of landscape protection. It distinguishes between protection and enhancement of the landscape, preserving the former in the State’s jurisdiction and devolving the latter to the Regions (Degrassi, 2012) together with the responsibility to approve a spatial (territorial) plan for the entire regional territory aimed at improving landscape quality. The Code states that the regional landscape plan must contain prescriptions (binding rules) aiming to preserve protected areas, but it does not prevent regions from introducing other planning measures, tools and devices in order to achieve these objectives.

A wide opportunity space is thus opened up for regions, requiring deep changes in planning approaches and tools (Marson, 2016). How to take up this challenge? How to foster and support a transition in the spatial planning system leading to landscape- and heritage-centred local development strategies in the place of old fashion pro-growth land use planning? This will be the research focus of this paper.

In order to tackle this issue a first question to be answered is what we mean by spatial planning system and how we conceptualize transitions in those systems. The issue is anything but simple as there are very divergent positions. On one side there are advocates of a regulatory vision of planning, centred on what has been defined ‘project plan’ (Albrechts, 2004, quoting Faludi and Van der Valk, 1994), who maintain change to be the result of normative, top-down command-and-control measures. Their idea is that through the enforcement of laws, regulation, standards, etc., change would trickle-down and spread in due course at the level of planning practice and territorial development projects. This approach has been widely followed in planning practice in Italy as elsewhere, while being hardly criticized for its ineffectiveness in contrasting dominant interests and in “making urban life more beautiful, exciting, and creative, and more just” (Davidoff, 1965, p. 432).

On the opposite side, for a long time now, completely different approaches to the definition of planning and – consequently – to the way changes may be produced in the planning system were attempted. Although embracing a varied range of perspectives, these approaches shared a process-centred (instead of a plan-centred) vision of planning (Davidoff, 1965; Forester, 1980; Friedmann, 1987; Innes, 1995; Healey, 1996). Their vision marked a shift in the interests from the technical dimension of planning to governance processes. Experiences of innovation in urban governance promoted by active citizenship and community-based movements started receiving increasing attention in planning (Douglass and Friedmann, 1998). This also led to a diversion of research foci from large scale realities to fine-grained, micro-scale experiences together with the idea that transformative practices in planning needed to be conceived of as bottom-up, insurgent processes (Sandercock, 2003; Friedmann, 2011). “Can neighbourhoods save the city?” is the title of a quite recent book on community development and social innovation (Moulaert *et al.*, 2010), whereas social innovation is conceived of as encompassing three main dimensions – product, process and empowerment dimensions (Moulaert and Nussbaumer, 2005) –, none of which is related to any technical form of planning.

But can planning really do without a plan? Despite hard criticisms on the limitations of plans, it's hard to say that planning does not need a plan (Neuman, 1998). This is even more evident in places like Italy, where the 'urbanism tradition' has long dominated and has led to the identification by law of a number of technical tools and plans, including landscape plans, which are still mandatory although innovations are needed in line with the ELC.

In between the two opposite positions outlined above, the authors of this paper adopt a perspective that consider spatial planning systems as socio-technical systems, i.e. systems whose technological dimension is closely linked and co-evolving with several other dimensions including policy, markets, scientific knowledge, changes in user practices and cultural meanings (Geels, 2004). Because of this, in the analysis of the research issue outlined in the paper, the MLP framework will be used, which has been developed within the broad field of innovation studies to analyse transitions of such systems (Geels, 2002, 2005; Rip and Kemp, 1998).

The paper will be structured as follows. Next section provides a description of the framework known as Multi-Level Perspective (MLP) together with a proposed adaptation of that framework for the research problem under scrutiny. This framework will be used in the following section for the case study analysis, which is about the ongoing transition in spatial planning strategies in the Apulia region towards landscape- and heritage-centred local development and the role played in this process by the new Territorial Landscape Plan (TLP) of the region. A particular attention in the analysis will be paid to the way innovative forms of management of landscape have been actually mobilized, supported and given long-term perspectives, while resistance to change of key powerful actors has been lowered throughout the development and the implementation of the plan. Some lessons learned will be drawn in the concluding section.

A Multi-level perspective on transitions of socio-technical systems

According to the authors of this paper, a transition in the spatial planning system leading to landscape- and heritage-centred local development strategies in the place of old fashion pro-growth land use planning may be considered a problem of transition of a socio-technical system, as several dimensions are involved and co-evolving in it. Its scientific-technological dimension includes planning tools for spatial strategies' development at different scales (including general and sectoral plans, masterplans, strategic development plans, etc.) and the evolution of disciplinary knowledge and skills owned by professionals and those involved in plan making. But in order to turn landscape and heritage in a cornerstone of planning practice, to work on the scientific/technological dimension of spatial planning is not enough.

Several dimensions need to be touched. There is a policy dimension made of policy instrument mixes framing spatial planning strategies as well as spatial policies directing territorial transformations. There is an industry dimension, linked to the many private developers and construction companies making their profits in public infrastructure and private building sectors. There is also a dimension linked to market/user preferences, in so far as private buildings and farming plots are sold on the market to consumers while public infrastructures, both in urban and rural areas, are collectively used by citizens. There is then a cultural dimension linked to the way local communities perceive their territory and develop their place consciousness and identity. There is finally an institutional/governance dimension, which is related to the institutional framework for spatial strategies development and to the role local communities have in spatial strategies' formulation and management. Any transition in the spatial planning system thus need to encompass a collective effort to re-imagine the territory and to define new priorities for development reaching the many actors dealing with landscape 'production', i.e. development companies, farmers, local inhabitants, government officials, technical professionals, etc.

Because of the intertwining of all the above mentioned dimensions in the spatial planning system evolution, we suggest the use of the framework known as Multi Level Perspective (MLP), which has been developed in the broad field of innovation studies to explain transitions in socio-technical systems (Geels, 2002, 2005; Rip and

Kemp, 1998). Nevertheless, as already done in the application of that framework to the analysis of transitions in urban regeneration policies (Barbanente and Grassini, 2019), we propose the use of a modified framework, which add an institutional/governance pillar to the original six pillars defined in the MLP literature. This is done because of the higher relevance of the institutional/governance dimension in urban studies compared to other sectors to which the MLP framework has been applied.

The MLP framework has been developed based on insights from evolutionary economics (Nelson and Winter, 1982), from sociology of technology (Bijker *et al.*, 1987; Hughes, 1987) and from neo-institutional theory (Giddens, 1984). In short, it frames transitions as the result of co-evolutionary and non-linear dynamics of change taking place within and across three levels (Geels, 2002, 2005; Rip and Kemp, 1998). The lower level is the level of niches, which act as ‘incubation rooms’ for radical novelties (Schot, 1998); in this level three important processes happen: different actors, involved in niche-innovation experiments, learn through cycles of actions, sensemaking and adjustment of cognitive frames (Raven and Geels, 2010); expectations and visions are developed and provide direction to internal innovation activities and to learning processes; social networks are built and strengthened to increase the legitimacy of niche-innovations (Kemp *et al.*, 1998; Hoogma *et al.*, 2002). The meso level is the so-called ‘socio-technical regime’, which embodies the deep-structural rules, cognitive routines and beliefs that coordinate and guide – in a Giddensian manner (Giddens, 1984) – perceptions and actions of all actors involved, i.e. engineers/technicians, policy makers, public officials, civil society, scientists, private developers, funding bodies, grassroots organizations, etc. Finally, the macro-level is called ‘socio-technical landscape’ and represents the wider exogenous context of macro-economic trends, deep cultural patterns, macro-political development, etc, which influences niche and regime dynamics while being beyond the control of individual actors.

Figure 1. Dynamics of socio-technical transitions according to MLP. Source: Geels and Schot, 2007.

According to MLP, innovations in socio-technical systems come about through the interplay between dynamics at multiple levels (see Figure 1), as far as niche innovations build internal momentum, with rules and user preferences becoming stabilized in a dominant design after a period of experimentation, and break through the regime levels thanks to ‘windows of opportunity’ opened up at the regime level due to pressures put by landscape development (Geels, 2002). This may create changes in the socio-technical regime, which may eventually influence landscape development.

While this framework seems particularly interesting for the analysis of transitions in spatial planning systems because of its capacity to explain changes doing away with simple causality and emphasising the importance of the interaction of multiple agencies and actors through different levels, it does not offer in depth explanations of the mechanisms through which existing regimes may be destabilized and windows of opportunities may be opened up. At the same time, there is not in-depth research on the way transitions may be intentionally supported through policy interventions, which seems a particularly relevant issue in urban studies.

In the attempt to shed more light on the influence of timing and multi-level interactions on transition pathways, Geels and Schot (2007) have identified four typologies of transitions ranging from more symbiotic patterns like transformation and reconfiguration pathways (which happen when niche innovations are added to the regime without disrupting its basic architecture), to de-alignment/re-alignment pathways (when windows of opportunities are opened while niches are still competing to find the dominant one), and to technological substitution (which happens when windows are opened at the same time when niches are ready to get momentum).

As much of the transition patterns seems to depend on the timing and wideness of the windows of opportunity and on the capacity of regime actors to resist to pressures exerted by those windows, a core question may be how to foster a widening of those windows and how to support their capacity to exert pressures on regime? Are windows opened only as a result of a ‘landscape’ event, which is by definition outside the control of individual actors, or that process may be somehow supported and accelerated by interventions of key actors involved in the transition of the socio-technical system?

Very recently some MLP scholars started analysing possible conditions for deliberate acceleration of socio-technical transitions (Kivimaa and Kern, 2016; Roberts, 2017; Roberts and Geels, 2019), thus recognizing the importance of planned policy interventions on transition patterns. They shed light on the way deliberate strategies and policy mixes may work: (i) to encourage the breakthrough of socio-technical systems from initial niches, and (ii) to lower the resistance to change from incumbent actors and powerful regime players (Roberts and Geels, 2019); to say in other words, their research focused on how policy mixes supporting transitions may include elements of ‘creative destruction’, i.e. they may involve strategies and tools aimed both at the creation of the new and at the destabilization of the old (Kivimaa and Kern, 2016). These contributions are linked to a more explicit acknowledgement of the importance of politics and power on transition pathways, which was largely under-theorized in initial conceptions of the MLP (Meadowcroft, 2011). For instance Geels (2014) recently tried to give a more nuanced picture of regimes by showing the plurality of actors embedded in it, together with the multiple types of power (instrumental, discursive, material and institutional) they use to resist to transition.

In this paper we take further these new research foci in MLP by analysing, in a MLP perspective, multi-faceted and multi-level strategies for the destabilization of existing socio-technical regimes and for nurturing niches as a pre-requisite for the transition of a specific socio-technical system. In the definition of these broader strategies we also refer to policy instrument mixes, as these were defined within policy analysis studies, in their move from a focus on single instruments toward a combination of procedural and substantive instruments for a specific policy (Howlett, 2004). Howlett *et al.* (2006, p. 8) used the well-known taxonomy proposed by Hood (1986) as an overall template for assessing the potential components of any policy instrument mix. According to the Hood's schema, government resources can be grouped under four distinct groups, depending on their reliance on nodality (information, being in the middle of a network), authority (legal or official power), treasure (financial resources),

organisation (personnel and structural resources). According to this schema, the statutory document, above defined ‘project plan’, is only one of the instruments that governments use to implement or give effect to public policies.

Towards a new conception of territory in planning and local development policies: the Apulia case study

The case study analysed in this section is about the transition in spatial planning strategies in the Apulia region towards landscape- and heritage-centred local development. That transition started in 2005, when an abrupt change happened in the governmental lead of the Apulia region. For the first time since the setting up of the Italian ordinary regions in 1970, a centre-left government started ruling Apulia, which so far had always been ruled by centre or right parties. It was furthermore the first time in Italy that such a centre-left government was led by a president of the Communist Refoundation Party. This abrupt change in the regional leadership brought deep changes in regional government visions, with the ambition to promote “a new development cycle based on the enhancement of tangible and intangible resources, set up by women, men, youth, and cultural and environmental heritage of the territory” (Vendola, 2005). The failure of the development models implemented or sought after in a ‘less developed region’ like Apulia during the entire second post-war period, aimed at supporting economic growth through imposed or exogenously inspired policies, had fed such a political change. This reflected Apulian society growing awareness of the environmental and social unsuitability and unsustainability in the long term of these models (Barbanente, 2011).

At that time, the Apulian spatial planning system was still essentially centred on (mostly old) municipal land use plans mainly concerned with the management of future (abundant) options for urban growth; besides them, there was a regional landscape plan passed in 2000 imposing a landscape zoning on the territory and normative restrictions on the use of individual natural beauties, while neglecting the other parts of the territory. Such planning system included all the key features of the Italian ‘urbanism tradition’, i.e. rigid zoning and codes and ineffective development control (CEC, 1997) combined with low levels of trust and acceptance of planning intervention in society (Nadin and Stead, 2013, p. 1551). This was partly due to the fact that planning rules were generally considered an obstacle to growth especially in a ‘less developed region’. On the other side, low social acceptance of planning rules was linked to the acknowledgement that main decisions in urban planning were mostly influenced by interested actors able to organize political and professional power in support of their own interests at the expense of collective interests. This, together with the entrenchment of familism, clientelism and corruption, was further undermining the foundation of the regional planning system's social legitimacy.

In this context, the new vision carried out by the new government, aiming to give rise to a new development cycle based on the enhancement of tangible and intangible resources of the territory, thus created an extraordinary opportunity for giving political centrality to urban and regional planning in a landscape- and heritage-centred direction. The new regional Territorial Landscape Plan (TLP), launched at the end of 2007 and approved in February 2015, was conceived of by the regional government as the essential instrument to face this challenge. As the ELC provided the TLP with a wider conceptual framework to shift the focus from private interests to the common good (Pedroli *et al.*, 2013; Settis, 2013), the TLP interpreted the territory/landscape as a product of social processes, which in turn shape the ways in which processes are set up and evolve. This view emphasises that territory/landscape is socially produced, and implies that the plan must be able to capture a multitude of social, economic and cultural factors involved in its transformation, to increase ‘place consciousness’ (Magnaghi, 2010) and to guide towards an identitarian self-recognition, the recovery of cultural, economic and political ways of achieving self-determination and the valorisation of endogenous resources, among which landscape also features (Magnaghi, 2011).

This approach required a radical change in the regional spatial planning regime. How to trigger and support change in such a way that it could reach the several dimensions involved in that socio-technical transition? Replacing the old spatial planning instruments with new ones would not be enough. A much deeper process needed to take place to reach all the many actors involved in and to start the construction of a new history in the collective interpretation and production of the regional territory. This was done through the manifold actions and strategies carried out along the different pillars of the socio-technical transition.

Along the scientific and technical dimension, transition involved manifold and complex changes. On one side, new analytical tools needed to be found to describe and interpret the territory and represent regional landscapes through multi-faceted and multi-disciplinary perspectives, with an emphasis on the specific characters and identities of different regional landscapes, including the ordinary and degraded landscapes as required by the ELC (Council of Europe, 2000, II, 23-25, 36.). This entailed a complex process of social production of the plan carried out by the inter-disciplinary planning team and the local authorities/engaged citizens/society, acting together for the common good. The team was composed of 15 young experts in architecture, engineering, geology, agriculture, forestry, history and archaeology, many of which holding a PhD. They set up the TLP office in the regional planning department, with the scientific coordination of Alberto Magnaghi, an academic activist planner, founder of the so-called ‘territorialist school’.

The social production process was anything but easy in a region of about 20 thousand square kilometres and 4 million inhabitants. Hundreds of informal meetings were held across the region, together with thirteen formal conferences in different cities and villages. An interactive website provided continuous information on plan-making progress and an on-line ‘Landscape Observatory’ was created to facilitate interaction between citizens and the planning team in order to grasp best practices in the promotion of landscape values and worst practices about landscape damages to be prevented.

On the other side, innovative tools had to be identified to pursue the strategic vision of the plan besides the traditional part, still made of a regulatory framework that used authority resources, i.e. rules which all public and private bodies are required to comply with in accordance with the provisions of the Code, in order to prevent ‘special’ protected landscapes from being further compromised by the usual practices of development planning (Legacy and Leshinsky, 2016).

Innovative tools, all included in the Strategic Scenario of the plan, identified by the new TLP to foster its strategy-oriented approach, encompassed seven Guidelines, five Regional Territorial Projects and a number of Experimental Integrated Projects. The latter were particularly relevant for the transition pathways undertaken through the TLP as they constituted small niches of alternative modes of description, interpretation and transformation of local territories-landscapes developed throughout the region.

Some Experimental Integrated Projects were seeds of alternative development found across the region in a scattered way, then supported and coordinated within the TLP strategy thanks to special cooperative agreements signed between the regional government and local authorities and/or civil society groups, to become demonstration cases across the region that showed that ‘doing things’ differently was possible. In this way, those little niches gained momentum and aligned to break through thanks to the strategic vision of the new TLP.

One such niche was the Paduli case. After a brief introduction of this case, in the following sub-sections we will focus on how the regional government defended and encouraged the development of niche innovations through policy mixes aiming to produce positive interactions with each other and to break the well-established regime in the policy field at hand. Then, we will highlight how some ideas arisen from one of those niches spread throughout the region, with different characteristics and emphases depending on the specific features of the territory-landscape involved, and gave rise to different, sometimes unexpected niche innovations.

An example of niche innovations: the Paduli grassroots experimentation

An alternative, heritage- and landscape-centred, development strategy for the Paduli area had been started in 2003 as a grassroots experimentation in the extreme southern part of Apulia, southern Salento, which is called Paduli because of the geomorphological depression that characterises its core area. This area is mainly covered by olive trees and surrounded by a crown of small towns (overall 30.000 inhabitants). With its 5500 hectares it is the most continuous and extended olive grove of Salento. Ten thousand trees planted without a geometric order, one next to the other, stand among a labyrinth of rural roads, canals, sinkholes, reeds, fragments of woodland. The area is affected by enduring migratory processes and consequent abandonment of traditional activities, aging of population, impoverishment of socioeconomic structure, and depletion of infrastructures. A higher percentage of workers than the regional average are still employed in agriculture. But many of them depend on public assistance and on the ability to find other non-agricultural sources of income to sustain themselves. The fragmentation of land and the predominance of family run holdings make this economic sector incapable both to compete with productivistic agriculture and to meet the increased demand for high-quality products. These features can only worsen the abandonment and degradation processes already evident in various parts of this rural area.

A participatory and empowering process started in 2003 on the initiative of a small group of off-site architecture students, and progressively involved ten municipalities and local inhabitants. It was conceived as an open process, freely accessible to people coming from outside and in which everyone could observe, criticise and propose their ideas about the problems affecting the area and how to solve them for a better future. This process continued for some years and led local inhabitants and the young promoters themselves to (re)discover the peculiar qualities of the rural core, which had been abandoned and disregarded for decades by younger people who lived in the surrounding small towns. An identity of a place discarded and condemned to a slow degradation, which reminded the inhabitants the deprivation which previous generations succeeded to jettison, gradually turned into a new identity of mysterious and unique place which had preserved its territory from the social and environmental disasters occurred in other parts of Apulia. The close interactions between the small towns and a rural environment, easily accessible to all the inhabitants, were being progressively recognised as factors of diffuse spatial quality, relevant components of individual and collective well-being to be maintained and defended. From this collective cultural process arose the idea that such unique territory-landscape qualities had the potential to suggest new path of endogenous development for this rural area. The ‘Paduli park’ was the design concept identified to hint at the need to protect the traditional agricultural use while promoting various forms of cultural, recreational, touristic activities. These were essential to integrate the agricultural income, create new economy, attract people from abroad, and induce the local communities to re-connect with and to take care of their environmental and cultural heritage.

Supporting the development of the Paduli niche innovations

The regional planning team, which at the beginning of 2008 had just started drafting the TLP and triggering its social production, grasped the process underway in the Paduli area as an interesting experience with respect to the TLP Strategic Scenario and included it within the Experimental Integrated Projects. Thus, at the end of the same year, the ten municipalities and LUA – Laboratorio Urbano Aperto (Open Urban Laboratory) – association, which in the meantime had been founded by the young promoters of the process, signed an agreement with the regional government of Apulia. The core objective of the agreement was the joint implementation of a ‘multifunctional agricultural park’ as part of the TLP. This favoured the development of the ongoing process, since it gave it recognition and visibility, and so ensured its continuity. Moreover, it facilitated information exchange between the regional and the local level and continuous help to the weak organizational structure of the small municipal authorities involved. Furthermore, the competitive bidding processes, launched by the regional government to provide financial support for the implementation of the TLP, gave municipalities and people involved in the Paduli

process the opportunity to enlarge their experience to the different dimensions of innovation at the base of the idea of ‘multifunctional agricultural park’.

In 2010 the ten municipalities adopted an integrated regeneration programme developed by a coordination unit involving their urban planning offices and supported and harmonised by the LUA association. The main initiatives carried out since then, as briefly outlined below, were financed by funding derived from various regional policies. In 2010, a project aiming at recovering the ten historical centres and connecting them through the Park of Paduli was co-financed by the region using the Apulia European Regional Development Fund (ERDF) Operational Programme 2007-2013. In 2011, thanks to the regional initiative ‘Urban Laboratories: old buildings for young ideas’ launched by the regional youth policy department and co-financed by the National Fund for Underdeveloped Areas (Fondo per le Aree Sottoutilizzate - FAS), local young people were involved in the reuse of five public buildings and of a municipal-owned olive grove of about 8000 sqm for experimental, innovative self-organizing activities. Under the name “Living the Paduli”, these include different initiatives in the field of hospitality and tourism, slow mobility, food and craft, agriculture and environment, cultural heritage. Furthermore, by drawing on other priority objectives of the Apulia ERDF Operational Programme 2007-2013, slow mobility interconnections of cycle and pedestrian paths and ecological networks were implemented. Finally, a project for the integrated management of environmental and cultural heritage was developed thanks to an innovative tool launched by the regional department of cultural heritage with the aim of protecting and enhancing the cultural heritage through local development strategies based on vision and objectives of the TLP. The emphasis on the ‘integrated’ approach hints at an idea of joint management of cultural heritage and activities, environmental heritage and local welfare services, which actively involves a wide range of social and economic local actors. All these interventions triggered a virtuous circle of social, technical and organizational learning. In the 2014-20 ERDF-ESF (European Social Fund) programming cycle, the Paduli group of municipalities placed at the top of the regional ranking of applications for funding received under the ‘Sustainable Urban Development’ program.

The idea of the ‘park of Paduli’, originally aimed to protect the environment, to support a poor local agriculture, and to promote the local cultural heritage for leisure and tourism, has progressively become a space (territorial, but also social and institutional) that is building a new economy and a new heritage- and landscape-centred local development model. This consists of a number of different activities deeply based on the social relations between people and place, which guarantees the reproduction of the essential conditions of well-being and social cohesion.

This process gradually destabilized regime perceptions and strategies of key actors involved in this deprived area. This challenge was indeed quite easy in the Paduli case for a number of reasons. First, in that context the interests at stake are weak as well as the actors capable of resisting the penetration of innovation. Second, peripheral areas feel detached from the centres of political decision. Therefore, the appreciation of the importance of the process going on in the area by the Apulia regional government increased the self-confidence of the grassroots groups who had promoted the process, and assured them recognition and support from local government institutions.

Figure 2. “Living the Paduli”: ongoing activities

Supporting the diffusion of the niche innovations

The regional government used different policy tools to trigger the transition in the spatial planning system towards landscape- and heritage-centred local development strategies.

In order to strengthen and give coherence to niche experimentations fostered through Integrated Experimental Projects, the regional government carried out several actions under the umbrella of the TLP. One of them was the development of the Five Regional Territorial Projects, which received inspiration and support from innovations experienced in niches. The Paduli case, for instance, strongly inspired the development of the Project called City-Countryside Pact, as far as this identified 5 ‘multifunctional agricultural parks’ for the valorization of the regional countryside and some other parks for the countryside refurbishment. The implementation of Regional Territorial Projects was then supported through several tools and policy instruments.

In 2013, in order to encourage the creation of multifunctional agricultural parks, the regional government launched a call for proposals. Eight municipalities located north of the regional capital city of Bari and included in the ‘Park of towers and hamlets’ placed at the top of the regional ranking. They proposed a feasibility study that interprets the park as a great environmental equipment of the metropolitan city of Bari, where the multi-functional agriculture is a key source for landscape protection, enhancement and improvement, in line with the objectives of the TLP. Thus the study proposes the preservation of open spaces in urban areas and the historical alternation of open and built spaces along the coast, the enhancement of historic rural landscapes, and the halt of land consumption. According to these objectives, the municipality of Bari approved an address document to modify the old land use plan centred on an expansionary vision of spatial planning in order to adapt it to the TLP. Its main objective was to “safeguard and enhance valuable agriculture areas located around the built-up area”, where the feasibility study provided for halting urban expansion and carrying out actions aimed at reconstructing a landscape in which agriculture can be developed to serve the citizens and increase biodiversity and the connectivity of the rural system. This decision was followed by a conflict with a developer who had proposed the construction of a settlement in the park area, in conformity with the land use plan. Thanks to a difficult negotiation promoted by the municipality, an agreement was reached on a development proposal that allows to limit the land consumption by redeveloping the urban margin and integrating the existing settlement, characterized by profound social and physical marginality, in a high quality ecological and landscape system.

In this more economically dynamic context it was much more difficult to break the regime: powerful coalitions of interest around particular issues or areas try to bend financial resources to their own benefit, preventing niche innovations from expanding and stabilizing.

Another resistance to innovation arose from planning professionals and public officials, which mostly considered the territory essentially as an abstract, static and functional space, as a mere physical support adaptable to accommodate and able to bear any kind of development. The implementation of an innovative plan such as the TLP required the development of new skills and competencies among these professionals and officials. For this purpose at the end of 2014 the regional department for vocational training, together with landscape planning department and professional associations, organised a specific training course that lasted six months and was attended by more than 1000 people thanks to the possibility of streaming connection with thirty locations around Apulia.

Interesting to note is that in 2013 another multifunctional agricultural park was promoted, explicitly on the model of the Paduli park and located in the same ‘landscape area’. The signature of a specific agreement among 24 municipalities and the Province of Lecce gave rise to the project of the ‘Ionian Greenhouse Agricultural Park’. This aims to promote quality agriculture and the protection of agricultural biodiversity on the one hand, and on the other hydrogeological safeguards, improvement landscape quality, ecological complexity and closure of resource cycles. Moreover, during TLP implementation, the process of niche alignment is continuing, as the

complete regime shift has not occurred yet. Other innovation niches arose after the TLP approval, during the adaptation of the municipal land use plans to the TLP. Among the others, Campi Salentina envisioned an use of the rural areas centred on quality agricultural production, and implying a shift from a productivist space to shared and multifunctional space. This vision stemmed from the Negroamaro Multifunctional Agricultural Park proposed by Campi Salentina together by with six neighbouring municipalities in the northern Salento as an Integrated Project in line with the LTP guidelines. This aimed to experiment new pathways of territorial development through the enhancement of landscape, historical and intangible heritage, focusing on quality agricultural production, greater collective well-being and new forms of welfare.

Conclusions

In this paper we have analysed the ongoing transition in the spatial planning system in the Apulia region from an existing 'regime', dominated by a pro-growth vision of planning, to a landscape- and heritage-centred development vision, in line with innovations requested by the ELC. The spatial planning system has been interpreted as a socio-technical system, thus the MLP framework has been applied for its analysis. The analysis has shown how the ongoing transition profited from an abrupt change happened at the governmental lead of the Apulia region in 2005, which brought deep changes in regional government visions, with the ambition to promote a new heritage- and people-centred development cycle for the region, based on the enhancement of its tangible and intangible resources. But the opening of this window of opportunity and the existence, at that time, of small innovation niches scattered across the region cannot explain the pace and width of ongoing transitions unless we acknowledge the importance of a wide range of purposive strategies and policy instrument mixes envisaged by the regional government under the framework of the new TLP.

Through the application of the MLP framework the paper thus has focused on the analysis of multi-faceted and multi-level strategies envisaged by the TLP in order to grasp and strengthen innovation niches while fostering a destabilization of the pre-existing regime. Transition has been shown as the result of a blend of interactive enabling, supporting and contrasting practices. On one side, innovation niches have been identified by the TLP and given longer term perspective through the development of the regional development strategies. Different tools and policy mixes were devised by the new plan throughout its development and, later on, during its implementation phase, to support the alignment of niche innovations towards the new heritage- and landscape-vision of the plan. On the other side, the new TLP tried to challenge strong power networks and old regime perspectives owned by key powerful players like private developers, technicians and public officials, as well as perception of places own by people at large, which were deeply challenged to engage in a collective process of place-consciousness and alternative local development.

In places where the regime was particularly strong and there were no grassroots resources able to trigger processes of collective rediscovery of place quality and revitalization of local economy, Experimental Integrated Projects were the tools through which the regional government promoted niche innovations in the attempt to break through the existing monolithic regime. They were intended as 'soft infrastructures' (Vigar and Healey, 2002) leading to collective representations of tangible and intangible local heritage through community mapping, and local community involvement in landscape interpretation, preservation and enhancement through eco-museums.

The transition is still ongoing in a piecemeal path made of some accelerations, with financial supports from the 2014-20 ERDF-ESF Regional Operational Program to innovative TLP strategies, and some slowdowns, due to changes in political governance at the regional level and the reorganization of technical structures at regional and state level. This might eventually lead to the establishment of a new socio-technical regime. But there is no guarantee of this, as the MPL analytical framework suggests by doing away with simple causality and linear explanations (Geels and Schot, 2007).

Abstract: The topic dealt with is the tangible and intangible widespread heritage located in the fragile areas of the northern Italy, crossed by the river Po. Here the idea of the line is defined through its thickness, that is the heritage that we want to discover and evaluate, and for which the line represents an opportunity to become a hinge, an anchor and a flywheel, in order to regenerate fragile territories. To undertake this investigation, we will use the VENTO cycle route as case study for applying this analytical approach. VENTO is a territorial project, designed by Politecnico di Milano and part of a network of paths on a national scale decided by the Italian Ministry, that uses a cycle route along the river Po as an opportunity to regenerate fragile areas from Venice to Turin. In this research VENTO proposes itself as an experimental laboratory which provides the possibility of reversing the work perspective on territory. This research, by identifying, mapping and trying to evaluate the heritage along VENTO, will investigate ontologically the relationship between fragility and heritage and how it can change according to this new perspective of the line.

Keywords: slow infrastructure; heritage; evaluation

Introduction. Which fragility, which heritage.

More than 60% of the Italian territory is occupied by small municipalities (53% of all Italian municipalities), where reside about a quarter of the Italian population (SNAI, 2013). These territories, which occupy most of the Italian territory, have been called "*inner areas*", defined as "*areas significantly distant from the centers offering essential services (education, mobility and health care), but rich of important environmental and cultural resources and highly diversified by nature*" (SNAI, 2013). The scarce offer of essential services, accessibility and work places characterizes the inner areas and it is the effect of a series of dynamics that emerged at different times and intertwined in various ways.

These dynamics were mainly due to historical phenomena and to some more recent ones. On one hand, the rural exodus from the mountain to the plain; on the other, in the lowland territories, the reduction of work places for the increasingly industrialized agriculture, which it does not offset by growth in industrial and tertiary employment. Then, more recent phenomena due to the crisis of some

industrial-type local economies and strong contractions of employment in large industrial activities caused by the process of automation, not compensated by the growth of employment in the commercial and tertiary sectors (Lanzani, Curci, 2018). The effects of all these phenomena are depopulation, emigration, social and productive rarefaction, the abandonment of the land. Already in 1961, the Italian agrarian economist Emilio Sereni had understood the extent of this transformation by speaking of "*a prelude to the disintegration of the agricultural landscape*". That gives us the idea that it is not only a physical phenomenon, but also a moral fact and a cultural result, of a descending story of places, people, memories. Antonella Tarpino describes these areas as "*spaesati*", that we could translate as "*lost*" and "*non-town*" at the same time, that means that they have lost the essence of a town (2012).

It is a continuous abandonment, a silent and latent phenomenon, which has led to the constant aging of towns and villages, to devastating effects on the hydrogeological system but also to the risk of loss of local identities.

In this heritage at risk, we can be able to find one of the cornerstones of the territorial rebirth of a vast part of our country. The word "*abandonment*", in fact, from the French "*abandonner*", has among its meanings that of "*making available to, referring to someone*" (Tarpino, 2016). Abandonment is not a final state, it often carries with it a symbolic and metaphorical significance of *re-birth, of return, of a second beginning*. The heritage of these places is intended as a broad concept, which includes material and immaterial elements, traces and signs that testify the relationships that the community has established over time with a territory (Zerbi, 2007) and that must be read and interpreted.

The tangible heritage is represented by: (i) immovable property, that is buildings, an underused or abandoned social fixed capital, often widespread in the territory in potentially strategic points (since they are unexplored); (ii) movable property, that means objects of domestic, religious or festive occasions. These are not disused or underutilized elements, but a complex of elements in relation to each other, affected by a phase of stalemate or crisis and no longer maintained today.

Intangible aspects represent a living heritage closely connected to the material one: the techniques and capacities that have enabled landscapes to be created, buildings and furnishings to be built and local products to be developed; dialects, music and oral literature that are derived from unwritten traditions, proof of the relationship between community and territory; types of organization of social life, such as festivals (Zerbi, 2007).

Then there are two categories of heritage that represent the perfect intersection between material and immaterial aspects. The first one is the agrarian traditional landscape (Barbera, Biasi, Marino, 2014), that is the product of natural and anthropic aspects and whose maintenance over time, as well as safety in hydrogeological terms, depends strictly on the continuity of traditional agriculture.

The second one is the heritage of food, that means products that are the result of an adaptation to the local conditions of climate and territory and to the cultural traditions of breeding, of working processes and of traditional kitchen. When an elderly person dies alone in one of these small villages, a story ends and with it they disappear a house, an era, a family, sometimes a surname.

Today we are all too focused on the transformation of the urban system, which is a laboratory of work and hospitality but also of inequality and marginalization, and we forget to look at what happens outside. The anthropology of abandonment, made up of empty spaces, abandoned or lost heritage, can be an opportunity to focus on the destiny of these villages and on the need for a new non-ideological planning, capable of rethinking opportunities for a new and sustainable regeneration of places and people (Teti, 2017).

1. Widespread heritage as a watermark of a territory. Intrinsic fragility and problems of protection.

“The concept of a historic monument embraces not only the single architectural work but also the urban or rural setting in which is found the evidence of a particular civilization, a significant development or a historic event. This applies not only to great works of art but also to more modest works of the past which have acquired cultural significance with the passing of time.” (art 1, INTERNATIONAL CHARTER FOR THE CONSERVATION AND RESTORATION OF MONUMENTS AND SITES, “THE VENICE CHARTER, IInd International Congress of Architects and Technicians of Historic Monuments, Venice, 1964).

Although many years after its adoption, the Venice Charter still shows a certain relevance, particularly in the definition of *“monument”*: it was a pioneer in transferring interest and attention from the object of *“historical and artistic value”* to the cultural heritage.

Buildings, landscapes, tools of everyday life, testimonies of the civilization that produced them for strictly utilitarian purposes: all these elements constitute the dense network of signs that make unique a territory. These elements despite of being fragile because no longer central to the life of a community and subject to degradation because abandoned, they can become the pulsating and lively center of the regeneration of a place, if adequately protected and re-identified.

Firstly, it is necessary to understand how the protection can be an action that acts as a driving force of a sustainable development for an heritage that is no longer 'exceptional' and single, but customary and widespread.

The instrument of the constraint *ex lege* for the protection becomes difficult to apply and manage when dealing with such large numbers.

Even if it were possible for a state to protect this heritage with national legislative instruments, the effectiveness of the policy should be always verified.

So what could be the strategies to put in place for the protection of widespread heritage?

Firstly, a depth knowledge without filters linked to the value judgment - historical, architectural, monumental, artistic, whatever it may be. A first important, but perhaps not yet sufficient action, partially done by many territorial bodies in recent decades, is the census of widespread heritage, to do without preconceived criteria.

An effective protection should pass through the awareness of the local communities of the unrepeatability, of the identity meaning and of the role that this heritage plays for their economy and their territory.

Respect for the heredity of the past, which translates into care for the same, should enter in the ethical dimension of community, to be able to translate into an effective, widespread and capillary new form of protection.

Already forty years ago the Amsterdam Declaration, promulgated by the Committee of Ministers of the Council of Europe in 1975, underlined the role that community had to assume in handing down its architectural heritage to the future. This role closely intertwined with the concept of Integrated Conservation: *“Integrated conservation involves the responsibility of local authorities and calls for citizens' participation”* (Amsterdam Charter, point 2).

In order to survive, cultural heritage needs to be recognized and loved: *“only if it is appreciated by the public and by the younger generation. Educational programs for all ages should, therefore, give increased attention to this subject”* (Amsterdam Charter, point i). Therefore, public awareness should

be among the priority objectives for those involved in cultural heritage, through specific educational programs.

The most recent Convention of Faro, introducing the concept of "*common heritage*", focuses the attention on the relationship between Cultural Heritage and Community, recognizing the latter an active and participatory role since its definition: "*cultural heritage is a group of resources inherited from the past which people identify, independently of ownership, as a reflection and expression of their constantly evolving values, beliefs, knowledge and traditions. It encompasses aspects of the environment resulting from interaction between people and places through time*" (art. 2a).

In international documents, local communities have assumed an ever greater role in the preservation of material and immaterial heritage. The promotion and dissemination of a care culture in the local communities plays a fundamental role in ensuring the survival of this widespread and fragile heritage. The 'education' of community to see its heritage and to recognize it as a scarce and therefore exhaustible resource, could be the most effective measure to guarantee its survival. The only prohibition imposed by the "*constraint*" is almost never sufficient. However, it is necessary to find the correct ways to transmit this message. Conferences, lectures or courses, although important to train and update those who already have professional skills in the sector, they are not able to reach the common population.

Working together with local communities with practical examples and starting to share a different awareness of cultural heritage with the new generations, both could prove to be effective strategies.

2. Which tailored suit for heritage in the inner areas?

The territories defined as "*slow*", not because of an index of delay but as a distinctive development factor, are characterized by a logic that is not economist and that cannot be measured with traditional growth indicators. The same character of the territory represents a determining factor of development. The different local development models have common characteristics, such as: specialization in a production chain or technology; strong synergies and internal interactions; a marked sense of belonging by local community.

The territory, however, cannot be expressed only in terms of infrastructures or as a static reality, but it is a place where the geographical and physical elements are linked to other elements.

Thanks to the initiative of the Minister of Territorial Cohesion Fabrizio Barca, the National Strategy for Inner Areas (SNAI, in italian) is launched in 2013, coordinated by the Agency for Territorial Cohesion, and it attempts to regenerate these places. The main objective of SNAI is the reversal of the demographic trend of these territories and it is pursued through two classes of actions: (i) the first focuses on adjusting the offer of essential services, so that means the pre-conditions for the territorial development; (ii) the second aims to implement interventions in favor of local development, focused to generate labor demand through the re-use and enhancement of territorial capital. Precisely in this last class of actions there are tools that solicit the valorisation of resources through a quality regenerative tourism. In the coming years, luxury will be made up of rare goods, such as time, tranquility, silence, security, conviviality and a healthy environment. All these elements are definition of quality. "*Quality can be seen hellenistically as an attribution of meaning: when an object or a service is of quality, they acquire a particular thickness in our eyes, an aura that makes them unsustainable and precious, regardless of the intrinsic value of materials*" (Nocifora, de Salvo, Calzati, 2011). Therefore, the philosophy of the slowness, which uses time not for sentimental or

ideological reasons but as a lens to know and deepen the sense of places and to build a relationship between hosts and guests, is the suitable suit for these territories.

Therefore, in order to give a rebirth to these territories, it is needed a true innovative capacity that: makes the identity stories recognizable; assigns a new use to the heritage; generates jobs and new economies. All this is a project: an innovative project of continuous and daily education to care and protection and of a sustainable, responsible, ethically oriented tourism, able to reactivate broken narratives. To follow this direction, it is evident the need for a preliminary re-education work to recognize the specificity and the patrimonial value, in the perspective of instructing research of history, roots, identity and civic sense.

Montanari declares that heritage can no longer be something *to be visited*, but rather it is something that *contains us* (Montanari, 2014). It is necessary to consider a reversal of perspective. The reversal of gazes and actions should be able to transform: the art from an object to pay to everyday life fact and the citizens from customers into visitors. It is this type of concept that can grow users who choose sustainable tourism on a cultural and environmental level and who associate tourism with an active education, rather than passive luxury (Montanari, 2014). Starting from this clarification, talking about a project in this context means speaking of a "*pedagogical project*". It means a continuous and daily education, inside and outside school, and a sensitive and attentive eye to the recognition of what has value, that can lead to protect and care in the most emotional sense. In its most ancient form, the word "*care*" comes from the Latin "*coera*" and was used in a context of love and friendship.

Caring arises when the existence of someone or something begins to have importance, then it begins the attention, the concern, the sense of responsibility. Therefore taking care of these places and their heritage, firstly it means (re)knowing them with a moral and practical look at the same time. It means dedicating actions and projects to a sustainable, responsible and educational tourism. A tourism that is a reciprocal positive exchange between residents and visitors, aimed mainly at: identifying and bringing back those individual diffused heritage to the depth of their history; having the ability to relocate them within a narrative that knows how to produce attractiveness; develop the ability to attract tourists aware of the dimension they are discovering; proposing the slowness of knowledge and respect; enhance the specificities, rhythms, flavors, emotions, stories and roots of the place; produce work and provide supplementary incomes to consolidate the presence of community, slowing down the exodus from their homelands (Nocifera, de Salvo, Calzati, 2011). That's can be a tourism that is an economic activity but it is above all a "*multidimensional cultural practice*" (Nocifera, de Salvo, Calzati, 2011): a balanced relationship of interchange between residents and tourists.

3. The regenerative power of the slow line.

Slow tourism has been experiencing particular success in recent years. More and more people are approaching slowness as a form of possible and positive mobility. More and more people are those who wish to practice a form of holiday using slowness, in the various known ways: on foot, by bike, on horseback or mule, in kayaks, with small boats or with a combination of these ones. Often using the railway network where slow mobility infrastructures are not.

If initially, a decade ago, these were isolated initiatives or limited to a few hundred cases or to certain geographical areas (such as the case of the Camino de Santiago in Spain or the Danube cycle route in Austria), today slowness has gone on to occupy a more important place in tourism. Relevant for numbers, but above all for high social positive effects, for low environmental impacts and for the

ability to activate or reactivate local and widespread economies, especially where none of them existed before or where they were very weak.

This is one of the questions we are most interested in keeping in mind. The lines on which the different forms of slow tourism can exist, can become real and effective backbones for the territory. Unfortunately, the excessive specialization of these tourist lines has segregated them in areas far from the design interest of those working on urban studies or landscape planning, of those who design public policies. Cycling is usually seen as a way to move and nothing more. Its design, at most, concerned urban design and in any case at a very small intervention scales. Going on foot too, except for those close to pilgrimages. Moving on horseback goes beyond the design imagination. All these mobility forms, alternative to cars, have been the subject of frivolous discussions, but it has never been thought that they could be the common floor for the triggering of a new territorial vision, a different model of sustainable development, a strategy to regenerate the fragile territories.

Urban and territorial planning know little about the possible role played by these slow tourism models. And little did they inquire. Therefore, slow tourism has never found its own space in the discipline. Just today, with great difficulty, is it making itself known and accredited.

From the comparative studies made in other European countries, in the case of cycling tourism, the regenerative potential has demonstrated, especially towards the weakest areas, those farthest from the metropolis and from the traditional economies. Germany boasts 45,000 km of tourist cycle paths built in just over 30 years and today has over 175 million vacation days spent cycling every year; 2.2 occupied in cycling tourism per 1000 inhabitants. In Italy we are far from these numbers: the employed are only 0.22 per 1000 inhabitants, despite the fact that the natural and artistic heritage is decidedly greater. What is lacking is the culture for these tourisms and the infrastructures that make them possible. Let's focus on the latter.

These are linear infrastructures. Long distance cycling in the case of cycling. Paths in the case of walking trails. And so on for other specific cases. In all cases, these have the forms of lines. Thin and light lines, without motorized traffic, safe for all types of travelers (starting with the less experienced), well signposted, connected with the rail and road interchange nodes.

Those lines are often ancient ones, such as the case of mountain paths or religious paths. Lines that are more recent are the cycle paths. In both cases, these real infrastructures however show very interesting characteristics for the territories they pass through. First, compared to traffic roads, high-speed railways and highways, they interact with the places they pass as they are permeable at all points and not only at junctions, tollgates and stations.

This first characteristic makes walking paths and cycle paths dialoguing lines with the territories, meter by meter. On the contrary, with highways, the territory is used by points and gates. Thus the small and medium-sized localities remain excluded from any possibility of being known and visited. In the experience of the high-speed travelers, the internal areas disappear. There, tourism gets thinner until it disappears completely. Yet those areas, those small towns, those villages do not lack beauty, historical heritages, good traditions, history and stories to be told.

On the contrary, slowness can be a strategic opportunity for inner areas as it becomes a sort of lens with which the person passing can stop appreciating details that speed erases. The infrastructures that allow the slowness can therefore be a great resource for the internal areas if well designed and equipped to allow those forms of slow tourism such as trekking or cycling.

Slow lines can become a new paradigm for territorial design. This, however, implies the effort to see a walking path and a cycle path not only as a mobility infrastructure, but as real backbones that give new meanings to the territories.

All this also requires a change of scale. When we talk about slow tourism on foot or by bicycle, we are talking about lines of hundreds and hundreds of kilometers. Continuous, comfortable for pavements, safe and therefore usable by all (for age and ability), equipped with signs and not shared with motorized traffic, as foreseen for example in the definition of Greenway, even if here the technical ambition is to have durable and more comfortable paths, able to hundreds of thousands people. If we want a generative tourism in terms of jobs and economy, we have to imagine something able to involve a lot of people, not just a few or a specialized category of people.

Besides the change of scale, the long and slow lines need a strong coordination on the territory. Tourism does not tolerate discontinuities, management changes and administrative fragmentation. When you walk or ride, the landscape is the interlocutor we are dealing with. A landscape where administrative boundaries are not necessary to the travelers, even less where they impose changes in the rules of use that tire the traveler. Those who travel slowly design a new geography whose backbone is the following trace itself. To guarantee this, the various stakeholders must learn to agree themselves, to work together, to cooperate, to choose design details that respect a single code. They must stop promoting each one himself, but they have to learn to promote each other and the entire territory dominated by the line. This need a project. The idea of the line thus becomes a new program for governing the territory and an opportunity for a cultural change.

The vision by lines implies a real cultural work to do together with the citizens and institutions. Cycles and walking paths cannot be born either by chance or following the tourist business, because this would contradict the spirit of continuity and cooperation of which the slow lines live.

This detail obliges us to review our way of designing and planning: no longer for points, no longer solving only the single issue in a precise place, but always looking a wider territory, a sort of ecosystem where everything is linked to everything, and by everything depends.

4. How to support territorial regeneration processes: multidisciplinary tools and methods.

The opportunities for strengthen territorial development by enhancing cultural heritage are not always consensual. Conflicts between the instance of environmental resources, landscape and cultural goods preservation, social, as well as economic regeneration, often arise (Oppio et al., 2015).

The complexity given by the instance of achieving multiple and diverse objectives suggests to frame a Multicriteria-Spatial Decision Support System (MC-SDSS) able to combine the potential of GIS – collecting, elaborating and representing spatial data by maps – with those of Multicriteria Decision Aiding techniques (MCDA) – able to support decision-making processes through the elicitation of both qualitative and quantitative objectives and to evaluate potential impacts of the options under analysis (Malczewski, 1999).

In particular, MC-SDSSs transform and integrate geographic data (map criteria) and stakeholders' preferences and uncertainties (value judgments) in order to obtain information for decision-making and an overall assessment of the decision alternatives (Ferretti, Pomarico, 2012). The ability of this integrated approach to both generate alternatives during the strategic planning phase and to compare them during the evaluation phase makes this tool suitable to deal with complex and ill-structured territorial problems (Dell'Ovo et al., 2018). Differently from monetary techniques, such as Cost Benefit Analysis (CBA) and Stated Preference (SP) techniques, whose aim is to find the most efficient solution with respect to the maximization of social welfare, MCDA provide decision makers with a comprehensive analytical framework to explore decision problems, by supporting the elicitation of different views on alternative courses of action. According to the comparison carried out by

Saarikoski et al. (2016), the main differences between MCDA and monetary techniques lay in these aspects: i) aggregated versus not aggregated options; ii) universal versus context specific values; iii) unitary versus conditional conclusions; iv) distributional issue and income asymmetries; v) individual versus social rationality; vi) interests versus ethical judgements; vii) representativeness; viii) biases.

Given the aim of supporting inner areas regeneration by cultural heritage along slow mobility routes, MCDA seems to perform better than CBA and SP techniques, especially in the distributional issues, being the stakeholders' preferences an integral part of the evaluation process, and in the inclusion of multiple dimensions of the problem, that can be accounted by monetary units, proxy measures and special scales, tailored to the decision context.

The advantage of MC-SDSSs is the use of GIS for mapping spatial criteria, sub-criteria and indicators and aggregating the results in order to show both the potentials and the critical aspects of the territorial context under investigation.

It is important to underline how the strength of suitability maps is given by the possibility to read the total result and the partial ones, according to the structure of the decision problem. By providing different layers of spatial knowledge, it is possible to point out where are weaknesses and to define tailored strategies to solve them.

5. Towards an Atlas of regeneration: the VENTO project for the implementation of a Heritage Recovery Model.

The large amount of abandoned or underused heritage present in the areas subject to depopulation arises the need to reflect on the implementation of a *line tourism model*, capable of regenerating fragile territories.

With this objective, the case of VENTO is used to set the first steps of a *Heritage Recovery Model*.

VENTO, the project of a cycle route along the Po river linking VENezia to TORino, conceived by the Politecnico di Milano, is a territory project based on the line values. VENTO experiences the paradigm for a different way of territorial design: a test for sustainable alternatives shaped for helping inner and fragile areas to have a suitable perspective.

Technically VENTO is a cycle and pedestrian route. But if it were only this, it would have failed its mission which is instead to regenerate those territories and make them visible, thanks to a slow tourism vision. Slow tourism, as it is defined here, let people discover existing heritage and stories and it make them understand that they have always been linked to each other, even if today we don't see them like this anymore. We are talking about a light line that is designed to be a narrative thread, able to sew beauty.

Obviously all this has been thought to start a slow tourism, that does not exist along the Po river today, able to: generate new jobs, slow down depopulation, create new economies with very low impact, save the beauty that still exists there.

With these and other aims, in 2010 born the VENTO project, which is now under construction after years of involvement of municipalities, regions and national governments. Today, thanks to an assiduous planning and participation work of the Politecnico di Milano, the VENTO project is in the financing and realization phase (www.progetto.vento.polimi.it), thanks to a funding program of the Italian State and in collaboration with the regions.

Along the cycle route, there are two cases of heritage recovery in favor of line tourism: Ostello dei Concari (Figure 1), in Bagnolo San Vito (Mantova) and the Locanda dei Pontieri or Ostello del Po (Figure 2), in Guastalla (Reggio Emilia). Both are recoveries of public isolated buildings that have

been restructured and have been object of a call for tender. With this virtuous example, which recovers heritage, gives it a new use, generates jobs and local economies, we aim to create a Heritage Recovery Model based on the line.

Figure 1 and Figure 2: Ostello dei Concarri, MN (left) and Ostello del Po, RE (right). Two virtuous cases of recovery of public buildings in favor of tourism on the VENTO line.

In this way, the part of VENTO relative to the municipalities of the Province of Alessandria has become a test to take a first possible step towards this model for cultural regeneration and the initial approach of an Atlas that has heritage as its center. The territory under consideration, mainly agricultural (the most widespread crops are rice fields, poplar groves and arable land), includes 16 small municipalities in the Province of Alessandria (14 have less than 2000 inhabitants) in the depopulation phase (12 out of 16 registered a negative rate of change population, data source: ISTAT 2001-2013). In this context of fragility, consistent with the picture described about the Inner Areas, the Po river flows in a natural area covered by the Park of the Po Vercellese Alessandrino. The Atlas is an opportunity to carry out a census inside the area of the Park, focusing in particular on that type of buildings suitable to play a role in the line tourism, from the point of view of location and volumes. Therefore, we talk about the traditional building typology of the agricultural landscape of the plain, the Cascina (farmhouse of the north of Italy), which represents the largest widespread heritage, unrecognized, underused or abandoned. Through surveys and subsequent checks on the land registry, 24 buildings were found that reflect the requirements (Figure 3); six of these are public, the rest is privately owned.

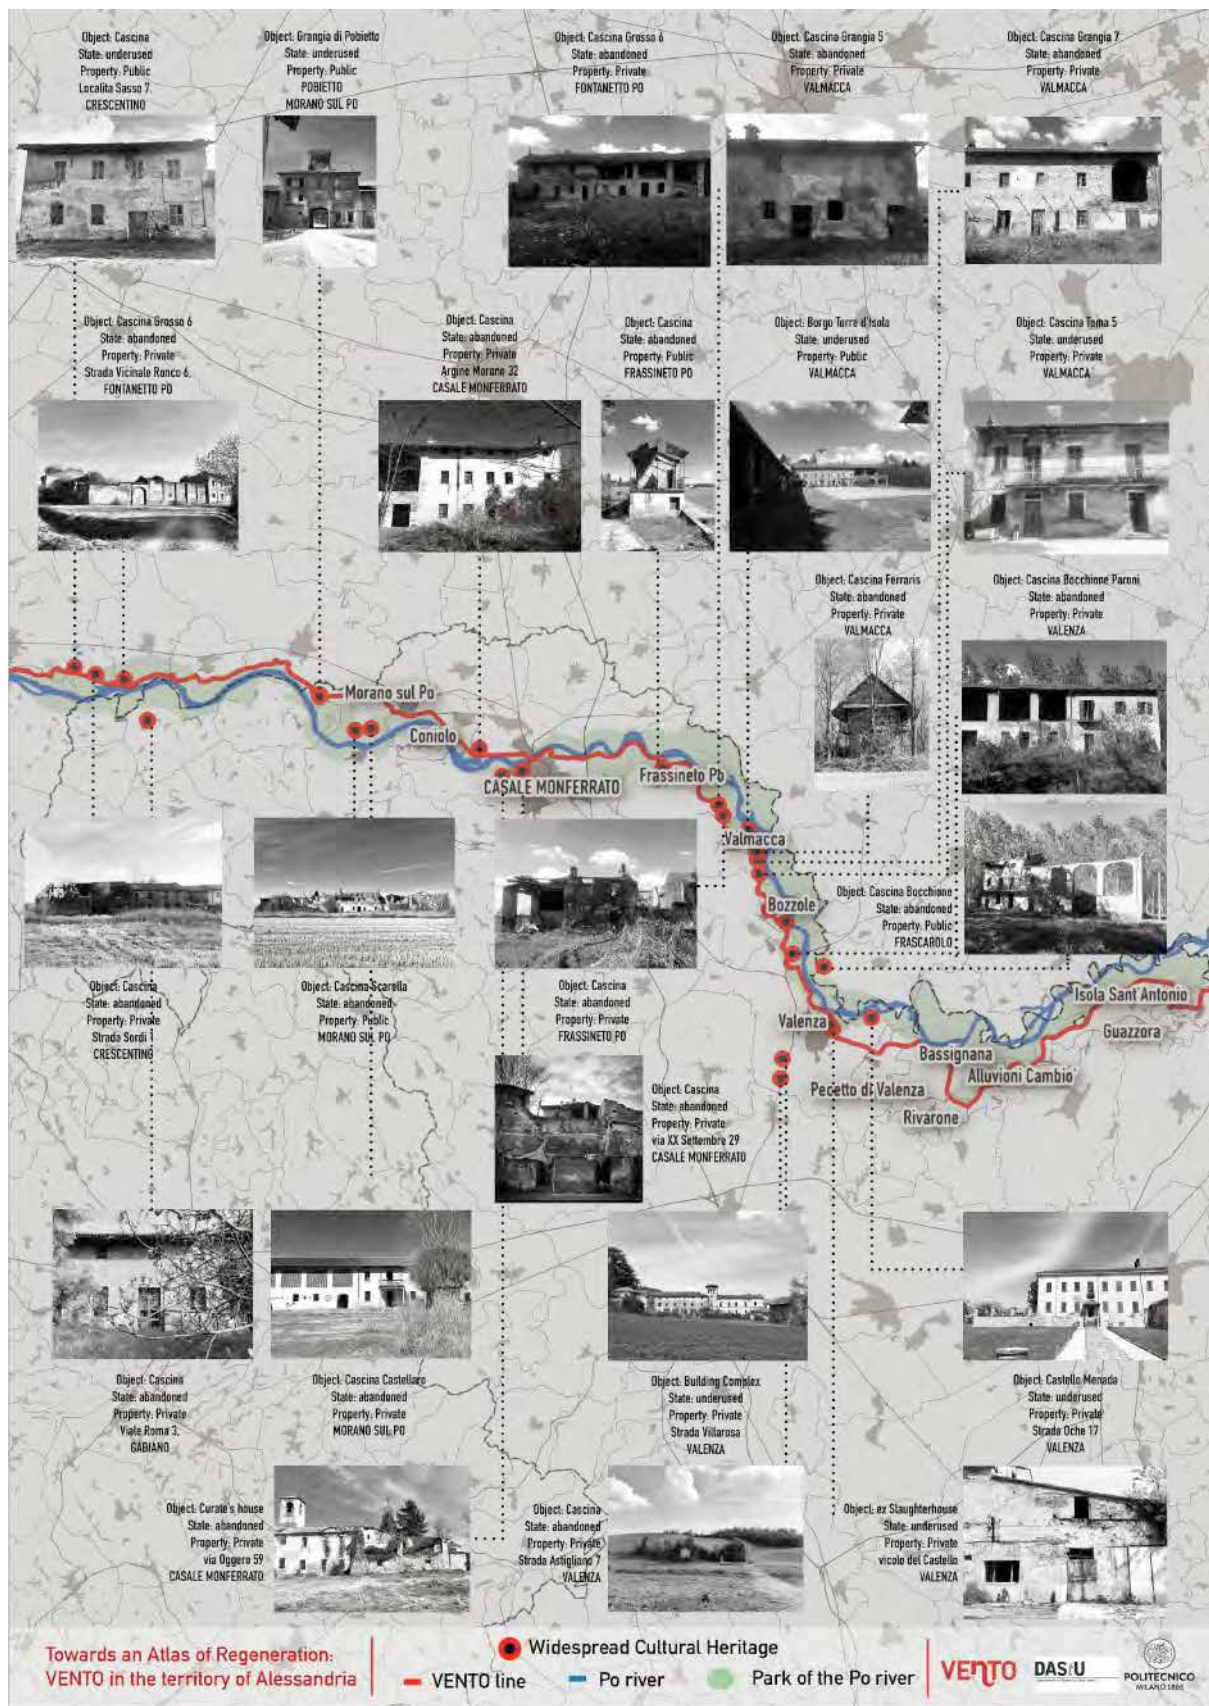

Figure 3: Towards an Atlas of Regeneration. Widespread Abandoned Heritage along the VENTO line in the territory of Alessandria (Figure elaborated by the authors).

The next steps focus on public buildings, identifying possible future scenarios thanks to the combine use of GIS and MCDA together, which allows supporting decision-making processes. Therefore, the criteria, sub-criteria and indicators will be identified on the basis of the research objectives. By aggregating the results, maps will be obtained that will show both the potential and the critical aspects of the area surrounding each building, helping to make the best choice based on the initial objectives of the research.

The model is proposed here in its first phase of pioneering approach to heritage recovery and it represents an experimental opportunity to investigate methods and tools capable of regenerating fragile territories, reactivating local micro economies based on endogenous resources.

Conclusions: scenarios and perspectives.

Attention to the cultural heritage in the Inner Areas is growing, primarily due to the damage suffered in these areas by the most recent natural disasters. Presence of people in small municipalities is a resource to protect the territory, especially for activities to contrast hydrogeological instability and for maintenance and protection of widespread common heritage. Therefore, there is a clear correlation between the SNAI, the redevelopment interventions of small villages, the contrast to the hydrogeological instability and the protection of common heritage, present here in large quantities (the places of culture surveyed in 2011 by Istat are 4,588, among them 1,803 are in inner areas). Furthermore, the SNAI indicates the tourism and the enhancement of heritage as a lever to reverse the depopulation trend in these places. The difficulties of these territories, linked to the lack of essential services, can be indirectly contained by instruments that could invert the negative indicators by creating employment opportunities and development. Therefore, small towns can become an opportunity to restart the economy, with an adequate consideration of the tourism potential and of the enhancement of heritage. Improved fruitability can act as an attractor for both inhabitants and visitors, contributing to territorial development. In the municipalities of the Inner Areas, where the degradation of spaces represents a further fragility factor, a gradual re-appropriation of places and a greater awareness of communities have a decisive impact on the actual success of policies. If were implemented policies for new governance tools and strategies for a profound educational renewal of the basic values, heritage could represent a driving force for development. That means, in some way, giving importance to the dialectical relationship between the singular, understood as individual, and the collective, on which the identity is based. Consequently, if we protect and take care of the context, or of what is collective, at the same time we take care of the individual. And that's why we take care of heritage: because heritage is of all and of each at the same time, we recognize ourselves and our identity in it; because a future without a past is an arrow without direction or orientation; because heritage is specificity, specificity is diversity, diversity is wealth; and finally, because heritage provides everyone the magnificent opportunity to *"start from the end"*, which means that describing depopulation places, apparently finished, as territories rich in potential is like declaring that the future can be changed. So it is possible to talk about a *"pedagogical project"* and in particular it is possible to do it thanks to the line: it places objects in a system, gives them added value and generates narratives by its nature of slowness. It is a project of coherence aimed at: the sensitivity of the individual in the community, the enhancement of the single object with respect to the line in which it is located, and in which the soul of places becomes the protagonist.

Research on the Renewal Strategy of New and Old Intersection Communities in Metropolis Based on the Concept of Landscape Urbanism——Taking a Practice in Shanghai Tianlin Community as an Example

Shufen Hu¹

¹*College of Architecture and Urban Planning, Tongji University,, lucy19930608@163.com*

Abstract: With the development of the economy and the progress of society, people's demand for the quality of human habitat is increasingly urgent. However, the urban development strategy adopted by China's rapid urbanization process in the past few decades has brought problems such as high-rise buildings, dark corners, and lack of quality public spaces. Especially the new and old intersection communities have become the accumulation of problems in various periods. The Tianlin Community in Xuhui District, Shanghai is close to the inner ring road of the city, integrating a new community with high-rise buildings and a dilapidated old community. A large number of people and so rich elements such as iron orbits, hospitals, parks, slums, modern residential areas and so on, in stark contrast to the closed space, rare public activities and lack of vitality. Landscape urbanism uses landscape instead of architecture to become the basic medium in the new round of urban development. Practice has proved that landscape is the only model that has the ability to propose effective solutions to the rapid development of today's society and the problems of urban transformation from gradual adaptation and alternate evolution. This paper takes the landscape urbanism as the guiding ideology, regards the landscape as the most basic element determining the shape and experience of the city, In response to the problems of low spatial quality and lack of vitality caused by the isolation between functional zones and within functional zones in Shanghai Tianlin community, the community update strategy of connecting urban fabrics, integrating natural and engineering systems, creating synergy of shared spaces was proposed. Reorganizing the area through "landscape infrastructure", creating new urban Spaces that meet the needs of the people and finally re-establishing physical and social connections.

Key Words: Landscape Urbanism; Community Renewal; Urban Design; Shanghai Tianlin Community; Vitality Creating

1 Introduction

From the 18th National Congress of China, the new urbanization with Chinese characteristics has been proposed, which means the transformation of urbanization from quantity to quality and from extension to connotation. The 19th National Congress pointed out that the main contradictions in China's society have been transformed into the contradiction between the people's growing needs for a better life and the development of inadequate imbalances. From this we can find that China's urban development is shifting from an increase in quantity to an improvement in quality. The original way of building renovation is no longer suitable. Landscape urbanism originated from the criticism of

postmodernism on modernist architectural planning in the late 1970s. It is considered to have a profound impact on the improvement of human settlements. Therefore, at the current stage of development and stage of China, there are Important guiding significance.

China has experienced 40 years of rapid urbanization development. In order to meet the needs of urban economic and social development, a large number of new districts have been built. The population density and construction density of the cities are in a state of rapid growth. However, due to historical reasons and the development of “cake-spreading” in some areas at that time, there were problems such as low floor area ratio, dangerous buildings, backward facilities and bad sanitation (Yang *et al.* 2019). At the same time, the rapid expansion of urban space has made urban construction land reach the ceiling. Faced with the shortage of construction land indicators, urban renewal has become the main way to meet urban space needs (Tang, 2015). Especially for the new and old intersection communities of cities, the particularity of their location has led to the accumulation of urban problems, which are the key areas for urban renewal.

Based on the full understanding of landscape urbanism and urban renewal, this paper takes the urban renewal practice under the background of landscape urbanism with a new and old intersection communities in Shanghai, one of the cities with the fastest development and the most urgent urban renewal in China. Practice brings some relevant thinking.

2 The development and practice of landscape urbanism

2.1 The origin of landscape urbanism

The origin of landscape urbanism can be traced back to the critical stage of postmodernism's modernist architectural planning in the late 1970s. The main background of its emergence was that there were more and more “decentralization”, no centralization, and high liquidity in the city during the industrial transformation. People moved away from the urban center and the urban population experienced negative growth. Industrial civilization brought serious environmental problems to the society at that time, causing great damage to the natural ecology, and the human living environment was worrying (Steiner, 2011, Weller, 2008). Under such a background, landscape is the only model that has the ability to propose effective solutions to the problems during the rapid development and the urban transformation of today's society from gradual adaptation and alternate evolution (Yang, 2009). The landscape is expected to replace the building as the most basic element of the new stage of urban development, helping people to rationally use natural resources, reshape the natural ecology and the relationship between man and nature. In the 1990s, Charles Waldheim, then deputy dean of the School of Architecture, Landscape and Design at the University of Toronto, first proposed the term “landscape urbanism” to describe a series of emerging theories and practices in urban planning and design.

2.2 The concept and connotation of landscape urbanism

In the article "A Reference Manifesto", Charles Waldheim, the author of the term landscape urbanism, defines the concept of landscape urbanism: landscape urbanism describes a way to re-integrate existing order in the process of contemporary urbanization. In this process, landscape replacement of buildings has become the most basic element of urban construction. In many cases, landscape has become a perspective window for contemporary cities, especially North American cities, and an important medium for urban reconstruction (Waldheim, 2006, Waldheim, 2016).

Landscape urbanism is some different responses of a group of designers based on the same values. In the face of cities driven by capital markets, urban design should no longer be based on the capital carrier of architecture, but should return to urban Ecosystem and human-scale to do the design, its connotation has the following characteristics:

First of all, the landscape of landscape urbanism is not the visual perception of the aesthetic connotation in the traditional sense, or as a natural space for the building. It regards all the existing objects (natural or artificial) on the earth and their visual and comprehensive interpretation of the state and space as a continuation of the spread landscape. It is a combination of nature and man-made objects, a multi-functional structural carrier of the city, and the connotation of the landscape has a large degree of expansion and development (Feng *et al.* 2013).

Landscape urbanism advocates the natural process as a form of design, fully respects the natural evolution process of the site, analyzes the texture of its evolution, and uses it as a basic integration into the design. This is an artificial way to create a near-natural artificial ecosystem by using natural elements. It is based on ecological principles to reconstruct the living environment.

Landscape infrastructure is another important feature of landscape urbanism. Most people's knowledge of infrastructure is gray infrastructure such as roads and bridges. People usually only consider their technical requirements and ignore their social, aesthetic and ecological functions. Landscape urbanism advocates the coordinated integration and overall construction of "gray infrastructure" with "green infrastructure" such as park green space and rivers to form landscape infrastructure (Zhai, 2010). The landscape infrastructure is comprehensive and complex, close to the diversity of contemporary society and environment, and meets the maximum needs of social and economic development as well as ecosystem service requirements with the least amount of land.

Since landscape urbanism was born to solve the problem of the decline of American urban centers, it is very suitable for the revival of the central city that is declining. When the city develops rapidly, the central area of the city declines, and it becomes a gathering place for all kinds of dirty behaviors. It changes the image of the central area of the city through landscape urbanism, stimulates the vitality of the central area of the city, and wins new development. In addition, because the landscape is more flexible, resilience, and less costly than buildings, it is easier to cope with the social problems brought about by economic structural changes.

3 Urban renewal of the old and new intersection communities of metropolitan areas

3.1 The background and connotation of urban renewal

Urban renewal enables urban land to be economically and rationally reused through substantial maintenance, renovation, and demolition, and strengthens urban functions, enhances social well-being, improves quality of life, and promotes sound urban development. Its purpose is to promote a region (including economic, material, social, environmental and other aspects) for a long time, and the approach adopted is comprehensive and holistic (Song *et al.* 2015). The ways of urban renewal mainly include redevelopment, rehabilitation and conservation, but not limited to these three actions.

At present, the development space of China's megacities is basically saturated, construction land is increasingly scarce, and there are a lot of land resources in cities that need to be revitalized, such as

dilapidated houses, abandoned industrial buildings, and inefficient space. According to statistics, the commercial properties amount of Beijing and Shanghai are underestimated to more than 10 million square meters (Qin, 2018). China's cities have entered the era of stock development from the incremental era. Urban renewal has become a major new growth point for cities, especially megacities, due to its important role in improving the efficiency of the stock land and space.

3.2 Urban renewal of the old and new intersection communities of metropolitan areas

The old and new intersection communities of metropolitan areas is a special area in the city and an important potential area for urban renewal and structural optimization. This area was originally a fringe of urban development in the past. It has a certain sense of history and some of the functions and buildings developed in the early days. This is an area where urban space is rich in content and urban functions are highly mixed. With the rapid development and expansion of cities in recent years, these areas have become special areas between the new city and the old city. Due to the influence of traffic location, land price and other factors, in the background of increasingly tense relations between people and land, the intersection communities of old and new areas has become a center of illegally construction and social problems. It is precisely because of its problems and the prominence of contradictions that in the wave of urban renewal, this area has gradually become a hot spot for urban renewal. However, market-driven urban renewal tends to benefit value, and the update project lacks overall coordination. At the same time, the update of high development intensity has inundated the original regional characteristics. The update method only focuses on the project site itself and finally destroys the integrity of the design and the original near-human experience scale. Finally, the street vibrancy is replaced by the depressed high-rise buildings. Therefore, in the new development stage of pursuing urban quality, the new and old intersection communities of metropolises are in urgent need of a new round of renewal. Considering that most of the areas have undergone a large-scale construction and renewal, small interventions and construction should be adopted to achieve regional regeneration.

4 Urban renewal practice in Shanghai Tianlin area based on landscape urbanism

Shanghai is China's cosmopolitan city. After 40 years of rapid development, the shortage of land resources has become increasingly serious. Shanghai's new round of master plan (2016-2035) puts forward the basic requirements for the strict control of construction land use in Shanghai's new round of urban development, aiming to achieve “zero growth” in the total construction land use of the city, which requires Shanghai to transform from urban incremental planning to stock optimization.

Tianlin Community is located between the outer ring road and the inner ring road. It belongs to Xuhui District of Shanghai and is close to the Xujiahui City Sub-center (Figure 1). This area was a gathering place for workers' villages and production enterprises in the 1980s and 1990s. It is now an urban community with a predominantly residential function. Due to the particularity of its location, there are new communities with high-rise buildings, old and broken communities, and even the coexistence of illegally built urban villages. Although the facilities are complete and the flow of people is large, this area faces problems such as space closure, rare public activities, lack of vitality, etc. The update practice introduced in this paper is located on the riverside of Puhuitang river in the Tianlin community. It is a 7-hectare plot with good resources and convenient transportation, but it faces many problems such as the isolation of both physical space and social space, as well as low space quality and

lack of vitality (Figure 2). Based on the concept of landscape urbanism, we try to use ecological and human perspectives to discover problems within the site or with the surrounding environment and then solve problems, and also reorganize the site and then create new urban spaces that meet the needs of the people to re-establish material and Social connection.

Figure 1. Location of Tianlin Community between and Design Site in Shanghai

Figure 2. Problems the Site Facing(Contradictions New and Old, closures, high-voltage towers in parks,inactive public spaces, etc.)

4.1 Connecting urban fabrics

Landscape urbanism emphasizes the extension of design thinking to the urban scale, taking the perspective from the spatial organization and arrangement within the original venue, the beauty and ugliness of the design form to the discovery and solving problem within a larger scope. The design considers the role of the site in a wider range and the connection with the surrounding area, and proposes to create a blue-green network to communicate with the surrounding, to create a non-motorized traffic network and increase the openness.

4.1.1 Create a blue-green network to communicate with the surrounding

In the greenfield system planning of Shanghai 2035 master plan, Puhuitang river, which passes through the site, is an important waterfront corridor, while the Dream Park on the other side of Puhuitang river is a greenland node (Figure 3). At present, the green coverage rate in the site is low, and a large amount of green space is used for parking. At the same time, the ultra-high waterfront buildings, waterfront fences and parking spaces hinder the penetration of the green landscape and cut off the continuity of the waterfront corridor. Therefore, the design creates a green corridor along Puhuitang river and leads it into the site by constructing a multi-level greening network including waterfront green space, big green space, little community green cube, and connections between different green spaces. And finally form a greening node (Figure 4).

Figure 3. The greenfield system planning of Shanghai 2035 master plan

Figure 4. A multi-level greening network

4.1.2 Create a non-motorized traffic network to communicate with the surrounding

At present, the site is a typical motor vehicle-oriented traffic situation in China, with only a small amount of chronic space and poor quality (Figure 5). In order to solve this problem and create a good chronic network, firstly, plan enough underground parking space to solve a large number of ground parking problems occupying the traffic space, and secondly design a network of walking and cycling networks (including increasing the bridge connecting the banks of the Puhuitang river). And also connecting with the surrounding chronic system. On this basis, through the design of the section and the improvement of the surrounding environment, create a high-quality non-motorized traffic network (Figure 6).

Figure 5. Current non-motorized traffic spaces

Figure 6. Designed non-motorized traffic spaces

4.1.3 Increase openness to form urban public nodes

The city's important green corridor, Puhuitang river, passes through the block, and the large urban park, Dream Park, should have become a public node of the city. However, due to the property rights of the park and the consideration of safety and management of the residential community, most areas of the site are surrounded by walls or fences, the closing rate is as high as 82%. And even there are high

fences on both sides of the river, which completely obstruct the view of people. What's more, the lack of bridges makes the two sides of the river completely isolated.

The solution is to open the residential area. Of course, it is not as open as many communities in Europe and America. This is incompatible with China's national conditions and people's perceptions. Many successful opening residential areas experiences in China have shown that opening up some public functions and closing small residential areas is a good way. At the same time, the landscape forms a system that is open to the outside world (Figure 7).

Figure 7. Case: Partially opened residential area Figure 8. Public functions promote the opening of site.

In addition, creating more public functions is also an important method. Transforming the old abandoned factory buildings into museums, cultural centers and businesses, and increasing the proportion of public green space, making the land function complex and open, and then becoming a waterfront public node serving the surrounding areas (Figure 8).

4.2 Integrating natural and engineering systems

Landscape Urbanism show interests in infrastructure and ecological functioning, its challenge to the nature–culture dichotomy and its promotion of creative assemblages, that it promotes hybridity between natural and engineered systems. For example, some experts have already introduced such features as SUDS (sustainable urban drainage systems) and reed-bed water purification systems into urban areas. And the artist-engineer Viet Ngo's lemna (pondweed) facilities, also designed to clean up waste water (Thompson, 2012). This design takes into account both the natural and engineering systems and try to exert the importance of landscape infrastructure.

4.2.1 Restore ecological function and balance

(1) Use a variety of plants

In the long-term urban construction, the builders consciously left some ecological space, but often limited to large-scale turf cultivation and single tree arrangement, the horizontal and vertical landscapes are single, and also affect the regional biodiversity as well as undermine the development of ecological functions and ecological balance. The design uses a variety of species and adaptable local species, in the roadside, waterside, parks and other types of engineering sites, in the plane, facade and other layers

of plant combinations to increase biodiversity (Figure 9, 10).

Figure 9. Diverse vegetation

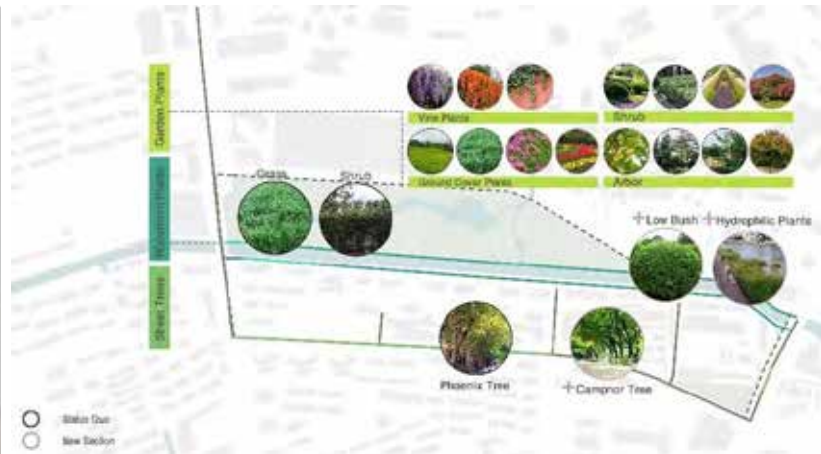

Figure 10. Rich plants configuration

(2) Create an ecological coastline

The water system is an important ecological element of the land and plays an important ecological role. However, due to flood control and safety considerations, the revetment treatment on both sides of the Puhuitang river has adopted a hard dam, and even surrounded by high fences. These rude urban construction not only affects the urban landscape but also destroys the ecosystem. The design uses natural revetment, which consists of natural slope, vegetation, natural stone, wood, etc. The ecological coastline is beneficial to protect the health of the water ecosystem, and it can prevent the erosion of water waves and floods on the shoreline. It can form a green ecological hydrophilic space and improve the landscape quality of the city's waterfront. Its berm, flood control, filtration runoff, self-purification of water enhancement, regulation of water level, and integration of waterfront plants with shoreline plants to form a complete river ecosystem are the best manifestations of integrating natural and engineering systems (Figure 11).

Figure 11. Designed ecological shoreline.

4.2.2 Redesign and re-plan the infrastructure

(1) The space under the high voltage tower

A major constraint affecting the role of the Dream Park on the other side of Puhuitang as its central park is the high-voltage corridor that passes through it. The huge high-voltage tower hinders the feeling of people in the park. In the case where the position of the high voltage tower itself cannot be changed, the space for the ecological and engineering functions can be created by redesigning the space under the high voltage tower. The specific means are to use the terrain to create visual attraction points, while using rich plant layout and artistic components to reshape the regional image to weaken the isolation and negative feeling brought by the high-voltage tower, and then integrate the new theme to re-energize the site energy, thus rejuvenating the vitality of the park.

(2) Green roofs of the buildings

The green roof is an important path for the effective integration of nature and engineering. Planting green plants on the roof can increase the green area; at the same time, absorb the rainwater runoff from the roof of the building, purify and filter through the plant roots, collect and store the rainwater through the rainwater pipe to the rainwater tank, and use it for watering or building water reuse; The planting layer can also protect the building skin, absorb building heat and alleviate the urban heat island effect (Figure 12).

Figure 12. Green roofs of the buildings

The infrastructure under landscape urbanism is not a high-performance mediocre urban machine, but a man-made organic system that enables the city to breathe freely, with a comprehensive and complex life, and more close to contemporary society and the diversity of the environment.

4.3 Creating synergy of shared spaces

Landscape urbanism is a concept that spans multiple disciplines. In addition to the practical functions of the traditional landscape, it also pays attention to the social function of the landscape. It

advocates exploring the spirit of the place, creating a space to adapt to the needs of the local people, and thus closer to the real and complex city, adding a human touch to urban planning. The design is based on the actual needs of the local people, and the space or facilities needed to be placed or replaced to create a humanized public space that can strengthen social interaction.

4.3.1 The built environment must enhance the social life

The design site is divided into four sections by four development entities (two residential areas, one kindergarten and one production enterprise), separated from each other by roads and walls. The public space within the entire site is only a few undesigned small green spaces, lacking public space for social interaction, and lack of regional vitality. In our field research, we found that people of different ages and different occupational types are active in this place, and they have different needs for this place (Figure 13). For example, children in kindergartens and communities need to play together, young people working here need a good working environment and a quality space for communication, and old people need to exercise and chat in the morning..... But they are very pessimistic about the public space assessment of the status quo (Figure 14).

Figure 13. Demands of different groups

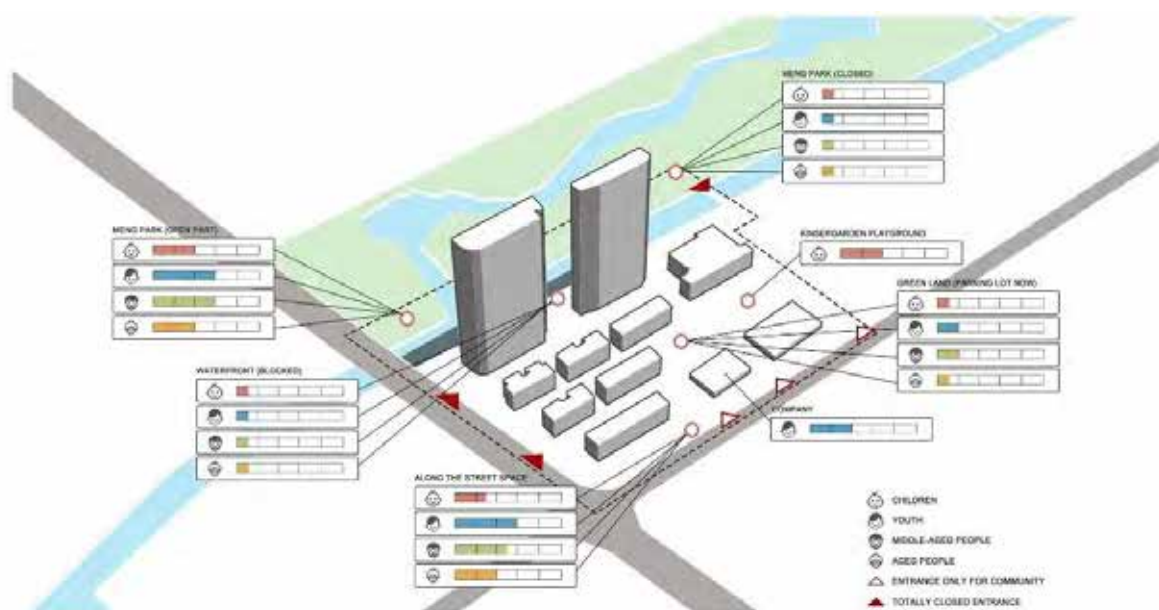

Figure 14. Spatial evaluation from different groups

The design predicts the space in which various groups of people may be active and the types of activities that may be generated, and then arranges these activities and people according to the space situation. At the same time, increase the corresponding facilities for the corresponding activities of various groups of people, and create a suitable space for activities (Figure 15). For example, set different types of game space for children of different ages, nursery and sand pool for children of 0-2 year old, graffiti wall and family coffee for children of 3-5 year old, and puzzle games and museums for children of 8-12 year old. These spaces that are truly suitable for a specific group of people can effectively promote people's activities here, thereby strengthening social interaction. They are mainly concentrated at the water's edge and a public space belt that extends from the water's edge to the interior of the city (Figure 16).

Figure 15. Activity spaces and routes for different types of people

Figure 16. A space that promotes social interaction from the water's edge to the interior of the city

4.3.2 Humanized scale public space

In the past period of time, China's rapid urbanization process has invisibly made society full of pursuit of scale and speed. A large number of simple and rude "non-human" scale space is produced, lacking space quality, unable to meet the actual needs of people, resulting in waste of space. Design site is also facing the same problem. Super-high residential buildings and large areas of artificial turf have

affected the use of public spaces. This design is based on the "human scale" as the basic ruler, focusing on small but exquisite, using the appropriate facilities and street furniture to make the public space more human, comfortable and secure (Figure 17).

Figure 17. Humanized scale of public activity space after design

5 Conclusions

Urban renewal has become an important direction and driving force for Chinese cities, especially large cities, in the new era of stock development due to the important role in improving the utilization efficiency of both stock land and space. The new and old intersection communities in metropolitan areas has become the key area of urban renewal due to the traffic location, land price and some other factors. Landscape urbanism is widely believed to have the ability to propose effective solutions to the problems of rapid development and urban transformation of today's society from the process of gradual adaptation and alternating evolution. Because it is very suitable for the revival of urban areas and can cope with the social problems brought by economic structural changes, it is suitable for urban renewal in the intersection communities of old and new in metropolises. Although the landscape urbanism theory has not produced much time and related practices are limited, its frontier nature will definitely make a great contribution to urban renewal during the period of stock development.

Acknowledgements

I am very grateful to Professor Xiao Yang for guiding us in the design workshop. I also thank the other professors for their suggestions. What's more, I would like to thank the design team members Acuña Alicia and Muñoz Laura for their hard work and other students in the big group. Their help makes me finally able to complete this article.

Abstract: There is a recent shift in focus in the design preservation and transformation of the built heritage from building objects to historical urban landscape in the Yorkshire region of U.K. The paper will discuss the conservation policies, design regeneration principles, approaches, and socio-economic impacts of two up-to-date exemplar projects -- ‘Albert Works’ in Sheffield in 2017, and ‘Square Chapel’ in Halifax in 2017. The paper points to a more culturally and socially-sensitive way of architectural design involving built heritage and historical urban landscape, which works with the as-found conditions of historical fabric and monuments, strategic design branding, economic returns in preserving and transforming the built heritage and landscape in the Yorkshire.

Keywords: Yorkshire; historical urban landscape; built heritage; design regeneration

Historical Urban Landscape

There is a shift in focus in heritage-led regeneration projects in the UK in recent years, from the focus on the single component of building and landscape heritage, or heritage conservation area, to an integrated and evolving historical urban landscape. The emergence of the conceptual framework of historical urban landscape, which was first put forward in UNESCO Vienna conference in 2005¹, has developed with its core concept in the UK based on Patrick Geddes’s urban heritage conservation of cultural landscape² and Gordon Cullen’s townscapes³. The spatial dimension of heritage has grown from ‘monument’ to the slightly larger concepts of site, thence to ‘setting’, areas and ‘landscapes’ and cities, and finally to the historical urban landscape. The various successive enlargements of ‘heritage’ have created an all-inclusive concept of the ‘historic environment’⁴. As Taylor summarized, central to the historical urban landscape are three underlying principles: understanding of the city as an evolving process -- living entity -- not merely a series of objects (buildings): here the idea of process embraces intangible cultural heritage values, *genius loci* and interaction between culture and nature; respect for the overall morphology of the city and its landscape setting so that future development does not overwhelm the landscape physically or its intangible meanings and values; understanding that conservation of physical material aspects of urban landscape must be balanced taking into account immaterial aspects to do with layers of meanings residing in the urban landscape⁵. The conceptual framework of historical urban landscape directs to a more holistic approach to built heritage environment in the UK, with an emphasis on the layers of historic and social values of those built fabric over time, rather than sticking to or returning to a particular time period. In this way, the UK has a subtle difference from, and beneath the surface difference there’s a very contrasting ideology with Viollet-le-Duc’s conceptual framework of restoration on historical built heritage and landscape,

as can be demonstrated from John Ruskin's statement on urban heritage fabric consists of varied assemblies⁶. Ruskin's principle and approach has a far-reaching impact in British conservation and regeneration from urban, architectural and landscape perspectives. Influenced strongly by John Ruskin, the Society for Protection of Ancient Buildings (SPAB) in the U.K, founded by William Morris and others in 1877, promotes that buildings should be preserved as found with minimal interventions, and any additions should be distinguished from the original one without confusing both statuses⁷. This point of view has also been reconfirmed in the Venice Charter, for example in its Article 12, stating that within restoration, replacements for missing parts must integrate harmoniously, whilst remaining distinguishable from the original as not falsify the artistic or historic evidence.⁸

Design Principles and Approaches

There are generally three design principles, associated with three design approaches, transforming built heritage and landscape in the Yorkshire region of England, U.K: the first is restoration, which refers to literal reconstruction to return or to represent the original characteristics in their fullest authenticity; the second is preservation, which refers to the minimal conservation of the as-found condition of the site and context, in order to maintain an alternative idea of authenticity and manage the future possible change. Its extreme version leads to a monumental-ization of heritage, which celebrates the vanquished past through the enhancement of ruin and decay; the third, a landscape-based approach, which is the topic of this paper and has become increasingly compelling within current local architectural professions and academia, seeks a point of balance and reconciliation between the old fragments and new additions, the past and future, the conservation and regeneration, through a sensitive and holistic design and planning approach. This approach to the built heritage often leads to a more culturally and socially resilient 'new-into-old' hybrid, which is not only focusing on the single historic built object or landscape zone, but on the layered, integrated whole historical urban landscape. It re-attaches significance and value on the reason and rationale to add, adjust and absorb the new contemporary addition in order to preserve the as-found historical urban landscape, which itself is not static, or authentic in rationalists' perspectives, but dynamic in process and responsive in use. This resilience embedded in a broader layering of urban landscape, rather than a single freestanding building object or landscape, is of highly strategic importance for heritage conservation and regeneration in order to manage the change in a sustainable way, both economically and socio-culturally.

To further demonstrate, two projects are selected for the following case studies, based on the three criteria: first, both projects were completed in the past three years, which should represent the most up-to-dated versions of urban landscape conservation and regeneration principles and approaches from Yorkshire region; second, both projects were initiated and done by Yorkshire local practitioners instead of national or global practice, which should express more specific locality and explain specific approaches to this particular region; third, and most important of all, that both projects approached and transformed very ordinary built field in a heritage context, ranging from not only the ordinary warehouse-to-workplace to the adaptive-reuse of disused hall at the building scale, but also their immediate surroundings at the level of urban landscape. Rather than those specially-proposed typologies in once-in-a-lifetime special commissions backed by strong patronages, these selected projects constitute the everyday fabric of an urban landscape and townscape, and would have more transferability to elsewhere in the Yorkshire regional context.

Albert Works in Sheffield, 2017

Figure 1 Before Regeneration

Figure 2 After Regeneration

Figure 3 New workplace's interior

In Sheffield, the largest South Yorkshire city, there is a great need and potential to regenerate post-industrial urban landscapes with many derelict warehouses and ordinary industrial buildings. Albert Works can be regarded one of the most successful regeneration projects in the recent decade. Located in the Cultural Industries Quarter, a conservation area designated in 2001, the warehouse building block of Albert Works started since early 1830s mainly for cutlery production (Figure 1). Although identified as ‘buildings of interest’ by the city council’s conservation team, the building had still been disused and abandoned for decades, until its renovation and conversion into a 1500-sqm digital company workplace (Figure 2) from the mid-2010s, done by Leeds-based architectural practice Cartwright Pickard Architects. The conservation policy of Cultural Industries Quarter highlights the high level of repair and recovery in the original building and the flexibility of new developments, in order to prevent the abandonment again. Built upon this foundation, the design team went beyond the contemporary functional fit of the historical structural shell, by reconsidering the role of this site for the city of Sheffield, which occupied nearly a full urban block with two street frontages. An architecture of urban interior – a double-height co-working hall (Figure 3) was realized, as an infill into the existing tight block through new steel structures and timber roofs. It provided a possibility for the new workplace to routinely open house as a social gathering hub for the historical neighbourhoods, in this way carefully sustained the historical social relationship between the original warehouse and its surroundings urban landscapes. In this sense for this heritage fabric, social process and spatial form were aligned within a piece of historical urban landscape. Down to the street level, the street-facing elevations of building block were restored and refurbished in its traditional red-brick construction, preserving the historical memory in link to the two existing streetscapes through sticking to the familiar form and configuration. However, the visual presence of two specific street elevations was articulated in a subtly-differentiated way into a contemporary moment, with a juxtaposition of contemporary brown-coloured metal and dark-coloured glazing with traditional masonry to capture contemporary change in this historical urban landscape. Behind the two street frontalities, the historical authenticity and future reversibility of this flexible contemporary working space (Figure 4) was as much ensured as possible by a series of light-weight plug-in furniture and the reuse of recycled shipping containers (Figure 5), with as less as possible structural touch and permanent link to the existing floors, walls and ceilings. Furthermore, a human-scaled landscape courtyard was designed to preserve the existing industrial chimney, again reinforced the site-specific heritage and place identity through new development and use from the point of view as a whole historical urban landscape. Albert Works has been very well received by its building users ⁹, local community and external visitors that its approach has become a benchmark for the following redevelopment projects in the adjacent plots to the whole historical urban landscapes of the Cultural Industries Quarter of Sheffield.

Square Chapel Arts Centre in Halifax, 2017

Figure 6 (left) Townscape of Halifax in 1988, with Piece Hall, Bradley Hall and Tower of church at the centre.

Figure 7 (right) Current streetscape of Halifax, view from the railway station and carpark area, most of the pre-industrial buildings have been well preserved as listed buildings by Historic England.

Figure 8 Competition winning model by Evans Vettori Architects, showing the new Square Chapel Arts Centre re-inhabits the left-over void between the Grade Listed I Piece Hall and Grade List II Bradley Hall buildings.

Located in the West Yorkshire, the town of Halifax had been heavily relied on the textile industry for hundreds of years before the dominant arriving of the industrial revolution. Halifax's greater cultural prosperity can be not only seen from its reputation as the 'Florence of the North', but also its

historical townscape (Figure 6) with two public buildings as its physical manifestation and centre – the Grade I listed Piece Hall built in 1779 and the Grade II listed Bradley Chapel built five years later. Piece Hall is a three-storey building containing as more as 315 individual units, and a central plaza providing market space also for trading pieces of cloth. The red brick building of Bradley Chapel has a typical Georgian front façade, sits adjacent to the key medieval street of the town as one of that sort of gate-way buildings along the street. The fates of both buildings went side by side with the family-based, hand-made weaving industry. Both decayed physically and mentally, and had been borrowed as Sunday school and informal settlements in post-war periods until its transaction back to the local community as an art space by only £25 in 1988. Theatrical and art performances went on regularly from then on, however without any spatial improvements of the buildings’ decaying social status and cultural role for the forgotten town. The situation of this piece of historical urban landscape has not changed until Matlock-based local architectural practice Evans Vettori Architects won an invited competition on this area which succeeded in finding out a lost and potential spatial link between the Piece Hall and Bradley Chapel. Their new design introduction of a new Arts Centre finally reinvented both heritage buildings back to a more welcomed and well-presented historical urban landscape branded for a contemporary Halifax (Figure 7). The team firstly got involved into the renovation of the central plaza of the Piece Hall, then identified a vacant triangle site in between the two listed building (Figure 8). Extensive community consultation then started, alongside with the discussions and meetings with the Arts Council and Halifax local council, to understand the value of the site as a part of historical urban landscape rather than a freestanding base or object. Both as listed buildings, there’s a very strict conservation policy and limited scopes for any renovation or redevelopment on the existing buildings’ interior and external change. The aesthetic, communal and heritage use value in the two historical buildings is so evident that any new contemporary addition would face how to preserve the as-found historical urban landscape without losing its contemporary development potentials. The resolved design from the perspective of historical urban landscape strategically put the new Arts Centre as a spatial linkage between the two listed heritage buildings, physically relinked through several pedestrian accesses and mentally relinked through a single continuous space covered by a single continuous roof. The roof derived its geometry and form from within the triangular site-specific in between two heritage halls (Figure 9), self-supported by three new steel structures in a resemblance of three old trees of the site, but also freeing any additional structural load to two enclosing walls from the two heritage buildings (Figure 10). The existing theatre was carefully refurbished with as much as-found elements conserved as possible; a new 120-seat auditorium was placed and hidden within a podium which also anchored the street pattern of the preserved medieval lane. More than doubled number of local users have been drawn back to this site for regular historical visits, art exhibitions and theatrical performances, or just a cup of tea with families and friends. From the original six founders, a staff of 55 now man the centre with 70 volunteers still coming in to do a shift, just because they want to. The new Arts Centre took £20k in their first opening week – the whole budget for this regeneration project was just £360k¹⁰. Here, the new Square Chapel Arts Centre not presented itself as a contemporary monumental building, but as a contemporary patchwork which was not only stitched into the existing historical fabric but also tailored the fragments between each existing components of this historical urban landscape as a whole. In this way, the sense of place and concept of heritage contexts for this historical gateway area of Halifax’s townscape were carefully maintained and sustainably managed in its most culturally-resilient meaning and approach.

Figure 10 Design regeneration based on contemporary spatial interventions working with the given walls, the left one from the existing Piece Hall and the front one's as-found back elevation of Bradley Hall.

Conclusion

The two selected cases in this paper open up a critical dialogue with the given heritage in the Yorkshire region of U.K through its transformative use for long-term sustainability as a part of an evolving historical urban landscape. The scales, conditions and effects of each case vary, but the design principles and approaches demonstrate a shared consistency towards a heritage-led regeneration with a broader perspective of historical urban landscape. Conservation and regeneration of built heritage and landscapes should be fast forward-looking, rather than merely looking back. It should be a resilient design process of managing change, which would be based on the strategic decision-making with a wider community on the as-found spatial resources and cultural continuity from a broader view of historical urban landscape. The championing of this shifting design principle and approaches in heritage-led regeneration projects should be based on a more evidence-based understanding that culturally-sensitive and resilient design can lead to a better understanding and preservation of the built heritage and landscapes, and can also trigger and direct the positive change and sustainable development of a locally-specific historical urban landscape. There is an urgent need to strike a point of balance, that both the historic authenticity and value and a sustainable future transformation for the built heritage and landscapes are ensured through conservation and regeneration of the historical urban landscape as large, by minimising physical interventions, by branding new strategic identities, and by embedding historical urban landscape as a continuous and constantly-changing whole. Within this fundamental principle and a series of diverse approaches tailored to diverse site contexts and external conditions, a strong counterpoint can be provided to those design forces that became rapidly and blindly involved in the ‘Disneyfication’ and ‘McDonaldisation’ of mass heritage tourism or tourism-led regeneration, hoping instead to readdress fundamental resilience within the built heritage and landscapes towards a historical urban landscape.

Abstract

This paper explores the relationship and impact between cultural mega-events and the subsequent production of other small and micro events held within heritage spaces. As with other types of mega-events, cities often turn to cultural mega-events for their perceived positive externalities and with a desired legacy that leaves a long-term impact on the city. These events generally build up and establish a strong reputation for associated network of actors that, in most cases, keep promoting smaller-scale events in subsequent years. In other cases, larger events crowd out small ones. Yet how do these cultural mega-events and all of their 'infrastructure' relate to and impact newly created or existing local smaller events? Additionally, what are the key impacts of continuous festivalization of heritage spaces in cities?

This paper presents and analyzes four found typologies of this interaction between mega-events and small localized existing or newly created events: "*Umbrellas*," "*Incubators*," "*Mothers*" and "*Killers*." We will consider in depth the European Capital of Culture program – since it has become an important cultural policy implemented across Europe for more than 30 years. "*Umbrella*" events encompass and include many pre-existing smaller events within the cultural mega-event. "*Incubator*" events also utilize pre-existing micro events, but come to enhance and grow them through the increased cultural capital, means and knowledge the mega-event brings. "*Mother*" events lead to the creation of new small and micro events in the city that did not previously exist, while "*Killer*" events have a negative impact on previously existing small and micro events. Finally, the paper theorizes on the mechanisms responsible for these typologies and their significance for urban heritage.

Key words: Heritage, Cultural mega-events, Festivalization, Cultural policy, Policy network

Cultural mega-events and the ongoing festivalization of cities

Cultural mega-events have become an increasingly popular choice for cities to host in the last several decades with the European Capital of Culture (ECoC) being one of the largest and most recognizable (Jones, 2017). For over 30 years more than 50 cities have hosted the event promoting a range of various themes and European identities (Ponzini & Jones, 2015). This and other cultural mega-events have grown in popularity for a number of reasons, but largely due to their reduced costs and lower impact on the built environment in terms of new venues required as it largely utilizes the existing facilities and cultural spaces of cities. In this way cultural mega-events are far more accessible to small and medium sized cities compared to Olympics, Expo or World Cups that have been rejected by many local citizens and city decision makers alike for their ballooning costs and perceived adverse effects (Jones & Ponzini, 2018). This decreasing trend has led to record numbers of candidate cities cancel their bids in recent years, a trend yet to occur in cultural mega-events. The popularity of the ECoC program has also spawned a number of similar spinoff programs that take place at global regional scales as well as within single nations.

One of the earliest spinoff programs was the Ibero-American Capital of Culture first hosted by Bogota in 1991 and has since been hosted by one of the members of the Union of Ibero-American Capital Cities (UCCI, 2019). The privately run American Capital of Culture initiative began in 1998 and has been hosted by one city a year since 2000 across the Americas (Capital Americana de la Cultura, 2019). The program is supported by The International Bureau of Cultural Capitals which is also responsible for the sub-regional Capital of Catalan Culture which began in 2004 in the small Catalan city of Banyoles. Other regional titles include the Arab Capital of Culture that started in 1996, the Cultural Capital of the Turkic World in 2012, the Finno-Ugric Capital of Culture in 2014 and the Cultural City of East Asia hosted by cities in Japan, China and South Korea which was inaugurated in 2014 (Christensen-Redzepovic, 2018). At the national level, City/Capital of Culture events can be found in the UK, Italy, Lithuania, Belarus, Slovakia and Russia. While many of these events are much smaller than the ECoC and are not equivalent in terms of funding or planning, they reveal the mass interest in hosting cultural events to boost the profiles of cities in order to attract investment, tourists and new residents.

Due to the nature of these cultural mega-events, considerations of their legacy can vary quite significantly from other mega-events. Sporting mega-events like the Olympics or World Cup tend to leave behind a very strong physical memory of the event due to the plethora of new stadiums, infrastructure and other built structures created specifically for the event. Meanwhile, much of the legacy of cultural mega-events tends to be more intangible. While there are examples of new cultural containers built as part of ECoCs or quite notably in the 2004 Universal Forum of Cultures in Barcelona, the desired changes or improvements relate to the perceived image of the city, management/governance structures or a new cultural sector that may introduce new uses into previously under used or abandoned areas of the city. One form that these processes can take place is through the ongoing festivalization of cities after they host a mega-event.

There has been discussion of the festivalization of cities within literature from various points of view (Richards & Palmer, 2012). This paper specifically examines the role of cultural mega-events initiating and growing this process as well as the unintended adverse effects it may introduce. The festivalization of cities can be seen as a desirable way to continue and extend the effects of a cultural mega-event past its close. With cities often wanting to establish new founded images based on culture following the event, the ongoing promotion of events and festivals is one such strategy to do this. This approach can also take advantage of existing cultural knowledge learned through the bidding, planning and implementation phases of mega-events. While at a much reduced scale compared to the initial mega-event, this post festivalization phase can easily utilize the newly generated expertise from the mega-event.

This new strategy can have a significant impact on the city, particularly for heritage spaces where a festivalization may introduce much needed new uses or add to the already high stresses from tourism. The paper proceeds by reviewing the existing discussion of the festivalization of cities through small and micro events in literature. It will then go further in-depth into the varying role that cultural mega-events play in these processes by presenting the four typologies: umbrellas, incubators, mothers and killers. These four typologies will be demonstrated through several cases followed by an analysis of the key influencing factors that determine how cultural mega-events can become one or more of these typologies. The implications of these typologies for heritage will then be discussed while the conclusions will identify some ways of working to verify these hypotheses and interpretations through more systematic analyzes.

International discussion on small and micro events

With the emergence of Leisure and Tourism Studies in the 1960s, the focus on events has become an important growing focus of study in more recent decades (Mair, 2012; Mair & Whitford, 2013). Foley et al. (2012) broadly outlined existing literature within the three strains of event management, event policy and event studies. Event management has long enjoyed a great wealth of instrumental studies intent on improving management approaches with a focus on event managers rather than local or national governance levels. Event policy posits events as part of strategies to improve cities and questions what makes events effective policies and what potential goals of these policies should be. Meanwhile event studies investigate broader socio-historic issues and relate to a number of diverse fields from the social sciences and share a link with leisure studies, which began in the 1960s. Getz (2008) defines the specific types of investigations into impacts on economic; social, cultural and political as well as environmental aspects. These overviews do not necessarily take account for the similarities or differences between literature on hallmark or mega-events and small to micro events.

For the most part, similar research has been conducted into small scale events as that of their larger counterparts. As noted by Getz (2008), a number of studies examine the economic benefits and impacts of small event and festivals, experimenting with a variety of methodologies to measure the spread impacts (Antonio Rivera et al., 2008; Baptista Alves et al., 2010; Bracalente et al., 2011; Egresi & Kara, 2014; Saayman & Saayman, 2004). Others have meanwhile focused specifically on small events' relationship with tourism and their ability to attract (or not) tourists (McHone & Rungeling, 2000; McKercher et al. 2006; Nurse, 2001). Meanwhile additional studies have been carried out on a range of social-cultural impacts (Robertson et al., 2009) as well as the sustainability of hosting small events (Small et al., 2005).

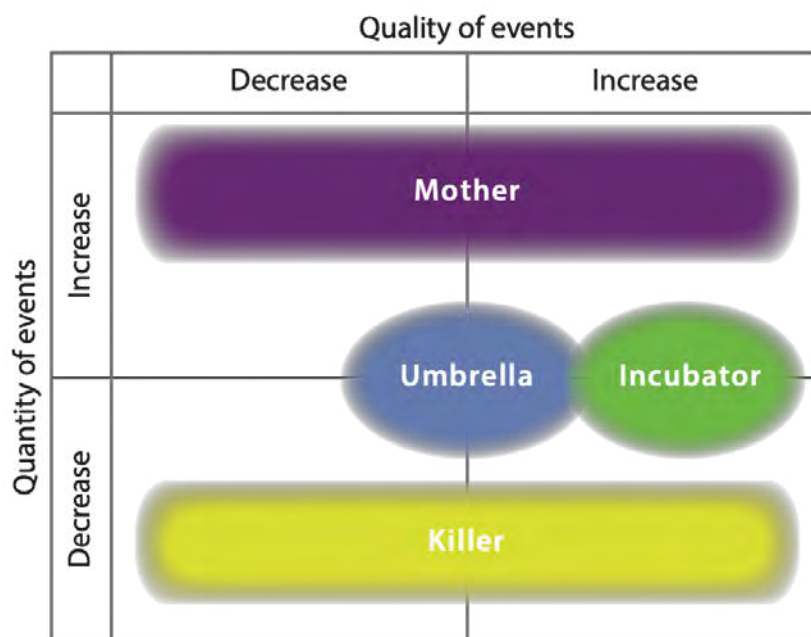

Of these studies with a wide range of research questions, one key point emerges in the study of small events: the importance of their local context. Several studies seem to confirm that small events in more rural areas or smaller towns have the potential to be more successful at attracting visitors and generating economic benefits than in larger cities. Studies conducted in global cities where additional significant heritage offers or other city attractions represent a much greater competition that smaller events have difficulty in remaining competitive (Egresi & Kara, 2014; McKercher et al., 2006). The reasons include the difficulty of advertising and attracting attention due to reduced finances, competition with other cultural offerings or their often clear focus on specific themes such as genres of food, music, film, etc. Studies focused on events taking place in smaller towns/cities found a higher rate of economic return and ability to attract visitors than larger global cities (De Bres & Davis, 2001; McHone & Rungeling, 2000). It should also be noted that the majority of visitors to small events/festivals tend to be more local or regional visitors with very few international visitors (in either small or large cities). Therefore, the impacts and attractiveness of these events should not be considered as being on par with those of mega-events. At the same time, small events and festivals tend to be

more sustainable than their mega-event counterparts due to the usual little investment required on the part of the hosting entity or city (Gibson et al., 2012). The differences in the impacts and effects of smaller events therefore also affects the planning, management and funding of smaller events and a direct transfer of approaches used for mega-events may not be useful or ultimately distracting in the organization of small and micro events (Kelly & Fairley, 2018).

The work by Kelly and Fairley marks an important consideration of the relationship between mega-events and smaller events. Their research focuses primarily on funding models and calls for further collaboration between event management and tourism strategies. However, existing research has not yet considered the cause and effect relationship between mega-events and a legacy of continuing smaller events. Despite the similar strains of research and methods of studying both mega and small events, they are primarily dealt with as separate phenomenon. The potential overlap or influence between one on the other is a gap that this research first identifies and secondly discusses within a specified point of view. This paper is therefore a first attempt to bridge existing studies between small and mega-events by considering the different ways that mega-events can encourage or hurt the continued proliferation of small events as part of its legacy and a consideration for its significance for urban heritage.

4 typologies and key influencing factors:

As noted above, cultural mega-events have become a growing phenomenon over the last several decades, coming to play an important role in the development of cultural policies and programming of cities. While notable for their singular, mass appeal, a key aspect that makes them appealing for cities to host is the potential to initiate long term improvements and changes. One aspect of this is the potential festivalization of the city through a continuation of small and micro events in the years following. The following four typologies have been identified as differing ways in which cultural mega-events can come to affect the ongoing generation of small events: *Umbrellas*, *Incubators*, *Mothers* and *Killers*. Table 1 illustrates these four typologies in their effect on the quantity and quality of small and micro events following the close of a cultural mega-event. *Mothers* or *Killers* focus on the quantity of events and could see either an increase or decrease in quality (however it may be assessed).

Tab 1. Mapping of the four typologies during the post mega-event period

Whereas *Umbrellas* see no significant change post-event in terms of either quality or quantity and *Incubator* types could be classified as a specific kind of *Umbrella* where a marked improvement in the quality of existing small and micro events can be observed.

Umbrella events are those that tend to encompass and include many pre-existing smaller events while hosting a cultural mega-event, but which does not leave a particular long-term impact on these events. The strategy of involving as many pre-existing events within the purview of the mega-event has been adopted by many cities hosting the ECoC and similar initiatives. The ECoC in no way requires the sole implementation of newly created cultural events as part of the year of celebration. In fact, cities are often awarded the ECoC specifically due to the fact that they are considered a 'cultural' city with existing cultural programs and events. Many of the cases that illustrate the other three typologies also implement a similar strategy during their host year in order to implement the greatest number of events during the year as possible. The defining feature of the *umbrella* type is that this grouping of pre-existing events fails to introduce any long-term impact or change. No specific learning is passed along or new networks created between various actors that foster collaboration or which benefit from a shared strategy. In this way the *umbrella* labels any and every event it can as being part of a year of culture, which may benefit the year, but which misses out on a potential long-term legacy. One example of an umbrella event is that of the Maribor ECoC 2012. The program for the year of celebration included various festivals that the city had already been hosting for a number of years and even decades in some cases. Examples include the Maribor Festival, Lent Festival, Old Wine Festival and the Maribor Theatre Festival, all of which have continued following the 2012 celebrations.

In a similar way to that of *umbrellas*, "*Incubator*" events also utilize pre-existing micro events, but come to enhance and grow them through the increased cultural capital, means and knowledge that the mega-event generates. *Incubator* events also bring together and take advantage of pre-existing small events, in some cases occurring for years prior to the mega-event, but which have been improved in some way through the experience and grown as a result in the years following. This learning may take place through a more strategic approach or introduction of cultural policy that was previously lacking. It could also happen through the continuation of the leading agency/foundation following the event. One example of an incubator event is that of the Milan 2015 Expo. While the main program occurred at the expo site located beyond the main urban fabric, a number of events were organized within the city center to coincide with the expo. This program was entitled Expoincittà, which the city of Milan continued to fund following the close of expo. In the four years since, it has gone on to create a database of event venues and sites for small and micro events throughout the city and periphery and now regularly organizes events throughout the year, including themed weeks that celebrate various topics including art, design, architecture, photography, food and many others. Milan previously had a strong tradition of events occurring throughout the year including the Fuorisalone Design Week, Artigianale Craft Fair, Piano Week and others. Expoincittà has been rebranded as YesMilano and has learned from the experience of organizing many events during the expo year, continuing and expanding in the subsequent years. The growth of leisure tourism is an evident ingredient that interested groups are exploiting, which can be seen through the festivilization and disneyfication of central places. Thanks to the institutional system and of information management strengthened through the organization of spread events during the year of Expo, the city has continued to support many small and micro events and increasingly spreading them throughout the territory. This appetite for big and small events and the strength of political constituency can also be seen in Milan's (along with the city of Cortina) candidature to host the 2026 Winter Olympics.

Unlike the first two types that are defined by the strong presence and use of pre-existing cultural events, *Mother* events are those that lead to the creation of new small and micro events in the city that did not previously exist. This is not to say that in *mother* events there were no cultural events existing prior to the mega-event but rather that at least some new

events created as part of the mega-event have gone on with some regularity. A clear example of this can be seen with the Liverpool 2008 ECoC and the success of the Giant Puppets event. The first event took place as part of the ECoC year in 2008 with a series of massive puppets parading through the streets of Liverpool, becoming one of the most iconic and memorable events of the year. It was so successful that the city brought the puppets back to the city in 2012, 2014 and 2018 along with other new cultural offerings. Other examples include the cases of the UK City of Culture Hull 2017 and the Mons ECoC 2015, both of which created organizations that have continued beyond the original event, guaranteeing new offers and long-term cultural events to which industry and tourist lobbies are interested. The continuation of the agency/foundation managing the cultural mega-event past the close of the event is not necessarily a requirement for *mother* events, but it is one of the key factors to be considered and which can make a significant difference.

The final typology to note are “*Killer*” events, which would be those that ultimately have a negative impact on previously existing small and micro events. There can be varying factors that explain such adverse long-term effects resulting from a mega-event. One key issue that can be observed in not just a few specific cases but in nearly all examples of cultural mega-events is the cliff drop phenomenon following their close. Due to the concentration of funding that focuses an extreme amount of resources for a short period of time, once the year of celebration is finished, there typically follows a period of greatly reduced budgets for continued events and cultural programming in the following years. This cliff-drop effect can have a quite severe impact on local inhabitants that go from an extreme period of festivalization to the other extreme of a non-festival atmosphere. Due to the year-long duration of most cultural mega-events, compared to other types of mega-events that last just a couple of weeks, the ECoC program can lead to a rather sudden change in the perception of cultural activity in the city. This effect may be particularly noticeable in smaller cities as compared to larger ones where there may be a stronger presence of pre-existing cultural institutions. This phenomenon can also result from a burnout effect where there is no longer a sustained interest in cultural events, on the part of organizers and audiences alike, following an intense year of activities leading to a loss of expertise (as managers leave to look for other opportunities, again particularly in smaller cities). Typically there is usually a slight reduction in tourism in the first year or two following a large cultural event. However, in recent years it has become more common for cities hosting a mega-event to have a legacy budget for the 2-5 years following the event in order to avoid the collapse effect of the cultural offer and to exploit the innovations introduced during the mega-event. While these legacy budgets do exist and can help in avoiding the drastic cliff drop off effect, these budgets are not always fully implemented as originally programmed as they require a clear legacy program to be already in place and cities are not always willing to continue their commitment to funding such efforts.

An example of a *Killer* event other than through the cliff effect of the event ending can be seen in the case of the 2009 Vilnius ECoC. While an exceptional case due to it coalescing with the start of the international financial crisis, the event underwent significant modifications due to a reduced budget and conflicts with management. In particular, the ‘People Programme’ portion of the event, which specifically highlighted local artists and cultural groups was essentially cut from the year of celebration (McCoshan, et al. 2010). Meanwhile, the more international and larger projects that had already been planned and financed were for the most part kept. In this instance, the local cultural scene was greatly affected, negatively, through the hosting of the event. While the event may not have been solely responsible as it related to much larger socio-economic challenges, it does demonstrate how in certain instances such mega-events can ultimately have a negative impact on the smaller cultural events.

Significance of ongoing small and micro events for heritage

The relationship between built heritage and mega-events has only recently become a field of investigation (Jones, 2017; Jones & Ponzini, 2018), the research into small and micro events

tends to deal specifically with heritage themed events and festivals taking place at festival sights (Coupland et al. 2005; Light, 1996). While there is an important connection between events celebrating local intangible heritage at or in local built heritage, this paper broadens the discussion to small and micro events of a wide ranging nature, heritage related or not. The first question this phenomenon raises relates to questions of authenticity and whether or not such events reduce the authenticity of such places and their connection with intangible heritage. Reducing heritage spaces to mere backdrops for any number of events could risk minimizing their value to that of any other public space in the city. However, on the other hand, from a HUL (Historic Urban Landscape) perspective, such a range of diverse uses and meanings introduced to these spaces through small events could serve as relevant tools to help connect and integrate them with the rest of the urban fabric of the city. Though not explicitly stated as a potential HUL resource (Bandarin & Van Oers, 2012), ongoing small and micro events could present one possible approach to revitalizing and connecting heritage spaces by bringing people to use and interact with them in new ways rather than being seen merely as places of tourism.

Regarding tourism, ongoing strategies of small and micro events likewise present potential threats or opportunities. For cities where heritage sites are already inundated by tourism, their ongoing promotion through these events may only increase tourism and the subsequent threats they bring in terms of overcrowding, loss of authenticity and use, gentrification, etc. Yet events also represent a potential strategy to help reduce pressure on heritage spaces by spreading them to other areas, potentially drawing tourists to less visited parts of cities. This approach could be combined with secondary or lesser known heritage sites as well, as has become common with former industrial structures, to encourage new uses as well as meanings and values for these places. While these issues are likely not the only possible impacts, they highlight the potential importance they pose for urban heritage as they can either become part of strategies to help ease the pressures put on these places while potentially also providing new meanings and uses or risk contributing to problems of over tourism. For these reasons it is valuable to note and better understand these phenomena and anticipate them as one of the possible legacies for cities choosing to host cultural mega-events and to incorporate plans for such events with heritage goals (Jones & Ponzini, 2018).

Conclusions and research perspectives

This article is a first step in exploring an issue that should be further expanded and better understood. We do not exclude the fact that there may be additional types and categories that would be useful to discuss the relationship between mega-events and small events. We are convinced that some issues clearly emerge from this typology of ours and that it is necessary to deepen the empirical analysis with more in-depth case studies and systematic data collection of various dimensions. As defined here, these four typologies focus on the post-event period, but a further expansion would consider the relationship with the pre-event phase as well. The political dimension in particular seems to be an important aspect given that the planning and management of mega-events can strengthen some groups and constituencies as well as create agencies and new actors that influence the following phases both in terms of governance and more generally in defining the political agenda of the city. Even the structure of cultural governance often evolves based on the demands of the mega-event and the years following. Further research could help in pin pointing more precisely the reasons why some cities continue to pursue event strategies following a mega-event while others do not. Such research would provide a clearer understanding of the roles that financing, political changes as well as potential cultural fatigue play in determining how and why local decision makers and stakeholders decide on particular event strategies for their cities.

The localization in space of new cultural life and attractors can have a significant impact on the regeneration of some areas and on their functional and social characterization; these aspects have sometimes been studied in relation to the mega-event and only to a lesser extent

with respect to minor events. An important aspect is once again the political. Considering in a more complex way the evolution of cultural policies and the development of a city downstream of a mega-event, the effects of gentrification and the festivalization of some areas, a question that remains to be asked is who benefits and who pays not only for the mega and small events in the medium term but also for the modification of the city and of the functional and social organization in space connected to the effects of major events. This paper raises these important questions, but calls for continued research and analysis to help answer them.

Reflections on Individual Memory in the Transformation of Cultural Heritage Cognitive Context

Cong Li¹ , Jiaying Li²

¹*Cong Li, Xi'an University of Architecture & Technology, 1411789043@qq.com*

²*Jiaying Li, Xi'an University of Architecture & Technology, 455811035@qq.com*

Abstract: From the perspective of heritage protection, world heritage and national heritage are undoubtedly the carriers of significant historical memory. compare to them our individual memory seems to be small and humble. The material and non-materials that condense human and national memory can be used as cultural heritage. Can the memory be re-recognized from the perspective of heritage protection? Everyone's life should be awed in the long river of history. This article attempts to explore the following three levels of content: First, The wild goose leads to stay a voice, the person leads to stay trace. The Importance of Individual Memory Presentation and Cognition; Second, The context of cultural heritage cognition and its transformation. Thirdly, with the change of cognitive context of cultural heritage, we juxtapose individual memory and major historical memory, and analyze and interpret them as objects. Based on this, supplement the relevant ideas, methods and principles in heritage protection and exhibition. While the historical heritage is recognized, the individual memory is superimposed thus the historical memories with human life.

Key Words: cultural heritage; cognitive context; context change; individual memory; memory superposition

Introduction

As far as cultural heritage is concerned, whether it is material cultural heritage or intangible cultural heritage, there are relevant definitions and evaluation criteria in terms of its form, characteristics and influence. They are undoubtedly the precious wealth left by history to mankind. World heritage and national heritage are undoubtedly the carriers of major historical memories. They mostly symbolize a major historical event or a great person. In the face of cultural heritage, a living individual appears humble and small.

The *Venice Charter* of 1964 mentions that "The essentials of historical monuments include not only individual buildings, but also urban or rural environments from which a unique civilization, a meaningful development, or a historical event can be found. This applies not only to great works of art, but also to some of the more earthy works of the past that have gained cultural significance at any time." From this perspective, the life and memory of each individual should be seen as an artwork. The memory that individuals or groups present in their lives is also wonderful and needs our awe. The recognition of individual memory in the perspective of heritage protection needs us to re-examine.

1. Cultural Heritage Cognition

Cultural heritage is a carrier that embodies significant historical memory. It is a trace left by humans or the country. This trace is for us to trace back and cognitive history, which is also the core of it. We can regard it as a carrier of significant memory or national memory.

The same is true for individuals. It is assumed that a certain space place carries people's lives and memories. When we walk from one place, we leave our figure and traces, when we look back or return to the same place one day. Can we find the traces of the past to connect our memories. When we return to a place where we used to live and grow, this feeling seems to be more intense. We will be curious to find the traces we have left. We try to soothe our hearts through it to seek and capture a sense of belonging. This trace condenses our personal memory, which we can consider as a carrier of collective memory or individual memory.

When we are reading the heritage, we tend to think at a higher level. What we show to us is often a significant memory. This material or immaterial is often linked to a farther point, which symbolizes a country or a nation, they are all great and important, but often abstract and summary. When we face cultural heritage, when we go to read it, we will have a strong sense of distance. Can we resonate as an individual? Whether we can be in it when we read it? Can it make an intersection and connection with our own lives? Hence, the context change of cultural heritage cognition has come into being.

2. Transformation of Cognitive Context

2.1. "Individual" in Context

Cognitive context is a cognitive network constructed on the basis of experience for schematization of a concept. It is the result of cognitive linguistic context, situational context and cultural context. The cognitive context of cultural heritage refers to the cognitive construction network of people in the field of cultural heritage specialty, which has strong universal recognition. People tend to think that cultural heritage is great and important, and put it in a higher position to look at, "individual" is often neglected. The transformation of cultural heritage cognitive context can be seen as a kind of adjustment or change of this cognitive network, that is, to put the life, memory and cultural heritage of individuals in the same important perspective to view and think, and individuals should be respected and awed. As far as heritage protection is concerned, it is not only to preserve and present important historical memories, but also to respect individual memories equally and establish a connection with our lives. Standing in front of today's heritage protection, we should explore the relationship between people and them. From the perspective of heritage protection to recognize individual memory is in the cognitive context of cultural heritage, the transformation of cultural heritage cognitive context is to explore such a relationship.

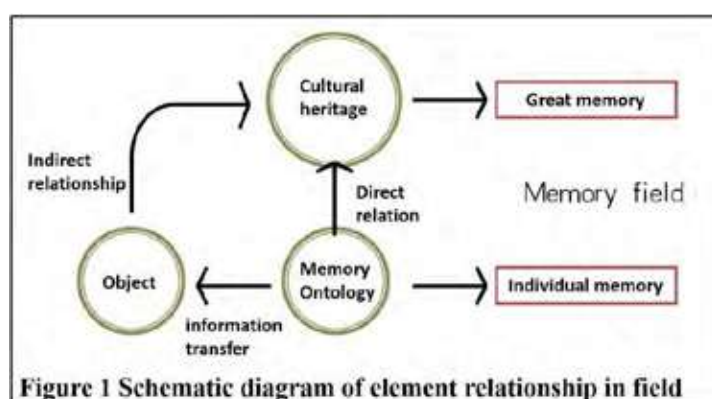

"Individual" is a relative concept, for a group, the individual is one of them, just like in the crowd, you, I, he is one of the individuals; for a larger scope, a certain "group" object can also be regarded as "individual", which depends on the cardinal number compared with it, when the cardinal number is large enough, the object becomes "individual". From the national point of view, "we" is the existence of individuals. "Individual" is not absolutely a quantitative concept. In some cases, it can not be judged by much. Compared with great individual figures, you, me and he are also "individual". Individual is easily forgotten.

Individual memory is small and humble relative to the important memory condensed by cultural heritage. It is often for a collective and individual. Therefore, individual memory is often difficult to be read by others and easily neglected. However, individual memory is strongly related to life and is specific and perceptible. It is a recollection of past life. We can also get a sense of belonging from it.

2.2. Memory Field and Field Relation

Individual memory and important historical memory condensed by cultural heritage constitute a memory field. There is a field relationship between them. In this memory field, there is a direct and indirect relationship between individual and cultural heritage (or a material entity). Major historical memories are condensed by the memories of many related individuals. It is an abstract summary of the memory of many individuals, and symbolizes the individual in an era and an era.

There is a direct connection between the individual (memory ontology) and heritage ontology in the same space-time; in most cases, due to time advancement, the individual (object) in reality and Heritage are in different space-time, at which time the two are mostly indirect. For example, as far as modern industrial heritage is concerned, workers (memory noumenon) who participate in its production and life are directly related to the industrial heritage, while the protection of heritage personnel or tourists are only indirectly related to it as objects; for the heritage with a relatively long history, the individuals who directly participate in it have disappeared, and the direct relationship between individuals and heritage has disappeared. The relationship between modern people and them may only be indirect.

There is a field relationship between individual memory and major memory, as shown in Figure 1. For cultural heritage (material entity), there is a corresponding "memory field". That is, there are overlooked individuals (memory ontology and object) outside the heritage ontology, which are often directly or indirectly related to them. Whether the individual in history

(memory ontology) or the individual in reality (object), they can also be used as a medium or carrier to transmit a certain historical information. The historical information they transmit may be related to themselves and heritage ontology. Many individual memories constitute this memory field. Heritage protection is not only to protect and display the cultural heritage itself, but also to protect and present the memory field associated with it, which is inseparable from individual memory.

Memory fields change over time. It is not difficult to understand that the closer memory more strong, and the farther memory more weak. That is to say, in a memory field formed around a cultural heritage, as time progresses, the memory ontology will gradually disappear, and the direct relationship between the memory ontology and the heritage will become weaker and weaker, and eventually disappear. When the direct relationship disappears and the information transmission from the memory ontology to the object gradually fails, the indirect relationship between the object and the heritage will disappear. That is to say, when the time is long enough, the connection between the reality and the

heritage will be broken, and it is difficult for people (objects) in reality to perceive and read it. In this case, the information available is also very limited. It can be seen that memory ontology plays an important role in information transmission. Only when the relevant memory information of memory ontology is effectively transmitted to the object or the memory information is effectively retained, can the indirect relationship between the object and the heritage be constructed, and the heritage can be more easily perceived by the object. With the development of time, the object tends to be more dominant in information transmission, and the indirect relationship will become more important for the recognition of the heritage.

Presenting individual memory emphasizes both "individual" and its relationship with history. The individual memory presented can be retrospected by the memory ontology and acquired by the object. Reading of the individual memory can close the distance between man and history, and it is more likely to make people connect and resonate with it. The wild goose leads to stay a voice, the person leads to stay trace. Individual memory should be presented and recognized.

2.3. Memory Superposition

Under the transformation of cultural heritage cognitive context, individual memory and major historical memory are juxtaposed to present and reshape the memory field which is composed of them. While historical heritage is recognized, individual memory is superimposed, which connects historical memory with real people's life and makes it easier to be read and perceived.

Memory superposition is to present the individual memory of memory ontology as an important part, and to superimpose the object memory which appears constantly in the course of time. The relationship between human and heritage (material entity) will become stronger and stronger, the relationship between human and heritage (material entity) will become more rich and vivid, and the readability of heritage (material entity) will be greatly enhanced.

3. Juxtaposition of Memory under the Transformation of Cognitive Context

Under the transformation of cognitive context, the display and presentation of national memory and individual memory are the core chapters, which are explained from two perspectives combined with design.

(i) As far as the long-standing heritage is concerned, taking the important historical memory condensed by the central axis of the Great Wall in Sui and Tang Dynasties as an example, this paper illustrates the relationship between individual memory (object) and it, aiming at exploring how individual memory as an object can be juxtaposed and connected with the great historical memory — Let the axis cross our life.

(ii) For modern heritage, Taking Shaanxi old steel mill as an example, this paper expounds the relationship between individual memory (ontology and object) and its relationship, and the display and presentation of individual memory, aiming at discussing how individual memory of ontology is presented in the field, and conveying information to the object — Memory factory

3.1. Let the Axis Cross Our Life.

The city is a living body, and Xi'an, as the ancient capital of the thirteenth dynasty, has a strong readability. Focusing on the axis of Chang'an City in Sui and Tang Dynasties, this paper initiates the thinking and design of the city, combines art and sociological knowledge from the perspective of planning to find opportunities to help people better read the history and reality of the city, so that the disappeared and buried axis and the historical text attached to it appear, so as to make it cross our lives and connect with life. And change people's reading behavior to make our life better.

3.1.1 Historical Background

The past dynasties have left a deep impression on the present layout of Xi'an City, among which the inner historical layers of the present city wall are the most dense. Through the superposition of historical layers, people can clearly realize that the historical memory connected by the axis as the national memory level is very rich. At the same time, we can see that the development and pattern of cities in different historical layers are closely related to the axis, and even have a great impact on the overall planning of Xi'an today. Axis not only affects the development of urban pattern, but also exerts a subtle influence on the life of urban people. As shown in Figure 2.

Figure 2 Axis Background and History Layer Overlay

The author clarifies the specific location of the central axis of Chang'an City in Sui and Tang Dynasties in the cities we live in through the changes of realistic geographical location and historical sites, and then overlaps the historical maps of the Five Dynasties, Song, Yuan, Ming and Qing Dynasties to the realistic cities. It is found that the once 150m wide and 5020m long Zhuque Avenue has been superimposed by urban roads and buildings in reality. In the overlapping of different histories, many memories have been broken or disappeared, among which national and individual memories are inevitable.

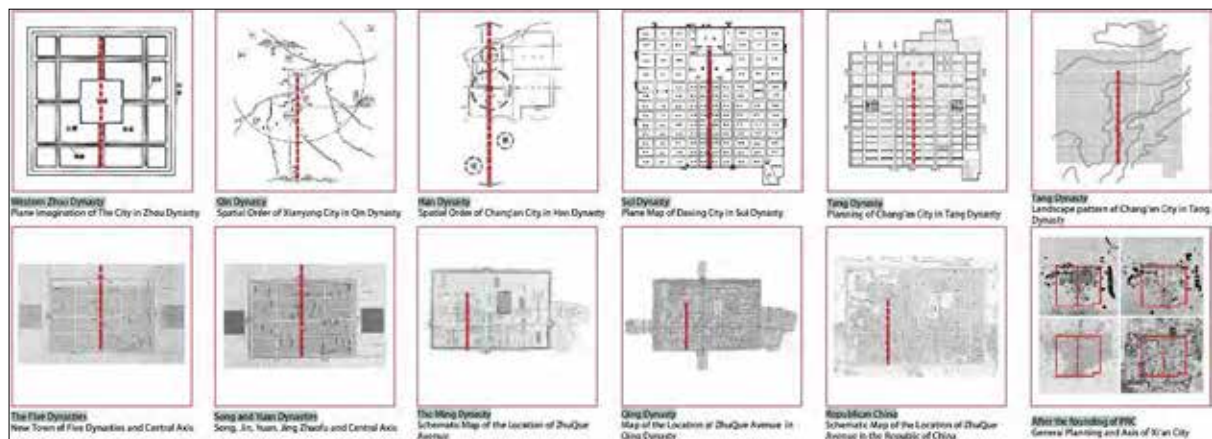

Figure 3 Diagram of Historical Change of Central Axis of Zhuque Avenue

As the ancient capital of the thirteenth dynasty, Xi'an is a famous historical city in the world and the eastern starting point of the Silk Road. From the Western Zhou Dynasty to the Sui and Tang Dynasties, the symmetrical urban pattern developed to the extreme. The axis is the center of Chang'an, which is of great symbolic significance. After the end of Tang Dynasty, the center of civilization shifted and the status of cities declined. Then to the great development of cities after the Republic of China and the founding of the People's Republic of China, cities began to expand on the basis of Ming City, and the central axis of the past gradually lost its former prosperity. As shown in Figure 3.

3.1.2 Evaluation of Historical Elements

The author also evaluates the historical sequence of the material elements (city, square, wall, door, street, etc.) and the non-material elements (characters, events, literature, etc.) that once existed in the corresponding historical position around the axis. As far as the distribution of dots is concerned, it is the history of fragments, that is to say, they remained in the historical layer at that time, did not continue, and were difficult to be perceived, as shown in Figure 4. These historical points appear and disappear in the long course of history like stars, fragments and fragments.

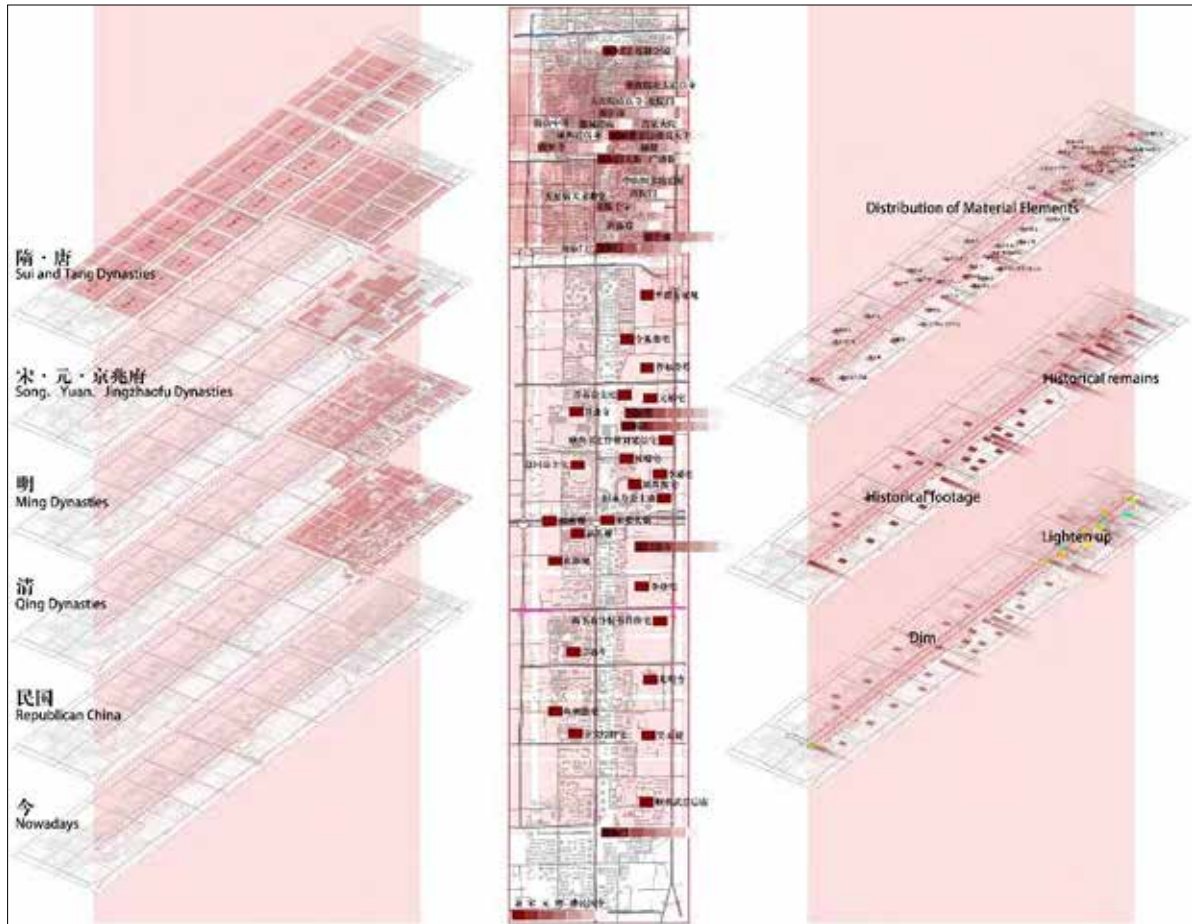

Figure 4 Historical Layer and Element Evaluation and Analysis Map

3.1.3 Realistic Elements

For the realistic elements, the author conducts site investigation on three important nodes on the axis of Chengtian Gate, Zhuque Gate and Mingde Gate. Explain from people's activities:

(i) For Mingde Gate, there is a breath of life on the site of Tang City Wall from morning to night, but people do not know the history. Nobody pays attention to what happened at their feet and beside Yangjia Village.

Figure 5 Mingde Gate Status Photo

(ii) For the Zhuque Gate, the activities under the city wall did indeed take place, but the traces of Chang'an City were nowhere to be found, and people did not think about history.

Figure 6 Zhuque Gate Status Photo

(iii) For Lianhu Park, the place where the Emperor once lived is now a pool of water. People are ignorant of the history of Taiji Palace and Chengtian Gate.

Through site investigation, the author finds that the places on the axis are different, but the cities are the same, and the historical layers are common, but the erosion of nature and human beings has led to the desalination of the axis and the separation of historical heritage and people's lives.

Figure 7 Lianhu Park Status Photo

3.1.4 Design Strategy

(i) Boundary qualification

In the concept of design, first defines the boundary, on the basis of the realistic map, defines the specific position of the central axis of Chang'an City in Sui and Tang Dynasties, and defines the 150-155m wide central axis by two boundaries of East and west. Subsequently, the most intensive eastern boundary intertwined with people's lives is chosen as the leading line to create this "line" in reality, as shown in Figure 8. Finally, the fragmented historical memory and the fragmented Chang'an City of Sui and Tang Dynasties are integrated with the reality by drawing lines, and the boundary is artisticized and presented by means of design.

Figure 8 Eastern boundary sketch

Let this thread pass through people's real life, through various scenes. Make people's lives intertwined and present the history that once disappeared.

Through analysis and evaluation, we can find that there are many historical elements on both sides of the axis, but the construction of reality has made most of them fragmented and disappeared. How can these historical elements, namely national memory, be read in modern urban life? In this kind of contradiction interweaving, the author holds the following two points of view: A. To make people re-recognize the fragmented history. B. While preserving the national memory, the individual memory of reality is superimposed, which enables the city to be read and stimulate people's reading behavior. Based on the evaluation of historical elements, historical layer and realistic layer, the concept of "line" integration is proposed. The "line" is used to connect all elements in series, which triggers people's reading of urban memory.

(ii) An Attitude to History

We have no experience of the past history. Inserting a virtual and totally inexperienced central axis and Tang Chang'an City in reality is a great challenge. History is a fragment, or an open or unopened box. It just provides reading opportunities and space. In the moment we enter this box, we will complete a crossing. At the same time, history is critical from a certain point of view, not illusory, thinking about history can hold completely different perspectives, each perspective can continue to deepen. Design itself only provides people with the opportunity to know and understand history, not to render history itself, but as a reminder for people to mark out, show people to think independently, so that history and people's real life contact. To inject new spiritual connotation into the original place

without causing damage or change. To a certain extent, people can resonate with history or find a sense of belonging.

(iii) The Way of Structural Line

A. City Image

This paper focuses on the state of "line" in the city to the perceptible scale, presents it in the way of city image, and makes dynamic city image from the two sections of Zhuque Gate and Little wild goose Pagoda on the axis to express the design. As shown in Figure 9.

Figure 9 City image screenshot

B. The State of "Line"

Through the selection of 50 scenes in reality, the author describes the position and state of the line. "Line" starts from Lianhu Park, crosses Lianhu Park from Chengtian Gate (as shown in Figure 10), then crosses Huifang along Tianjie (Chengtian Gate Street), then crosses communities of different ages along Kaihua Fang (as shown in Figure 11), then crosses Zhuque Community along Xingdaofang, then crosses Xiaoyan Pagoda along Anrenfang, then crosses Second Ring Expressway along Jingshan Fang, and then crosses Yintaicheng along Lanling Fang on Meridian Road. ... The author chooses two interweaving points of life scenes and history to show the state of the eastern boundary from the perspective of human beings, which is also a further expression of the line crossing.

Figure 10 Lianhu Park (Chengtian Gate)

Figure 11 Zhuque Community (Kaihua Fang)

C. Creating "Line"- Behavior Practice

The description of the state of "line" can illustrate that it interweaves closely with people's life and is vivid, and further demonstrates the necessity of the emergence of "line". In order to make people feel the existence of the line, the author selected five typical nodes of Lianhu park (as shown in Figure 12), City wall park (as shown in Figure 13), Zhuque Community, Xi'an Museum (as shown in Figure 14) and the south side of Yintai Ziwu Lu (as shown in Figure 15) to create the real line. The following selected sections record photos for illustration.

Photo Example 2

Figure 15 South Side of Yintai, Ziwu Lu (Lanlingfang)

Photo Example 1

Photo Example 2

We can intuitively feel people's life and reading behavior from these photos. The overall value of this event is to make a historic street in Tang Dynasty fragmented or disappeared coexist with the life of contemporary people today. The emergence of "line" makes life more interesting by adding a little spice. The emergence of "line" really changes people's urban life. The "line" interacts with contemporary life. It juxtaposes individual life with Chang'an City in Sui and Tang Dynasties. The emergence of "line" also changed people's behavior, let people know that when I crossed this "line", I entered the Sui and Tang Dynasties Chang'an City Zhuque Street historical space.

D. Node design

Taking the implantation of 10 nodes as an example, this paper establishes the corresponding reference mode and design template through its text presentation and "line" design method, and establishes the corresponding environment optimization system. The first step is to select the typical nodes, prompt and classify the elements through which the axis traverses, evaluate the different types of space, and then determine the typical nodes and design them as an example. As shown in Figure 16.

The selected nodes are the green space of Lianhu Park, the pedestrian space on both sides of West Street, the public green space of Nanyuanmen, the Zhuque Gate Section of Huancheng Park, the courtyard space of Zhuque Community, the Xi'an Museum, the west square of Shaanxi Stadium, the reading Plaza of Xi'an Jiaotong University and the central green space.

The spatial content of "line" is extremely rich and complex. It can not be presented by only a few nodes. The following scheme is only an example design of nodes.

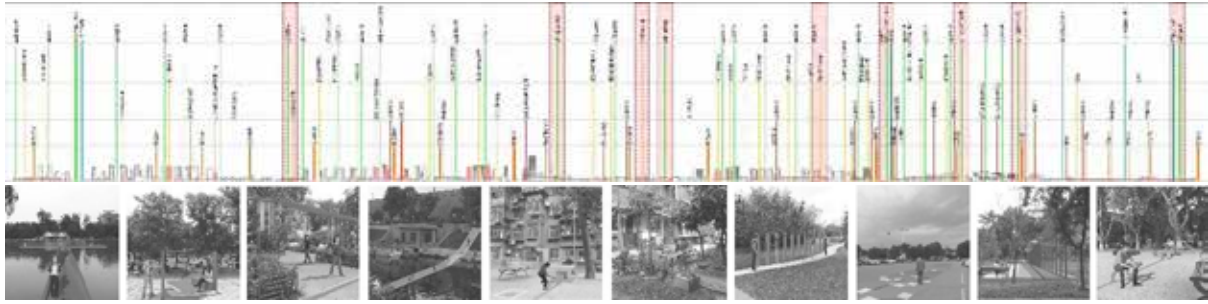

Figure 16 Node Selection and Node Design Diagram

3.1.5 Brief summary

Author does not think this design is complete. What is presented now is just an example. The author through the relevant design of the central axis of Suzaku Avenue, even in discussing such a relationship. Axis does not pass through the city, but through our life. A forgotten historical axis is actually hidden in our life, but it is shielded and buried. The function of "line" is to make this disappeared and buried axis appear and connect with life. "Line" should be passed through our life. The design focuses on the description of real life. Through the "line" implantation, we can give them a new spiritual and cultural connotation through a line, which is otherwise insipid and unrelated. It gives the real life a new thing, enriches the real interest and enhances the participation of the crowd.

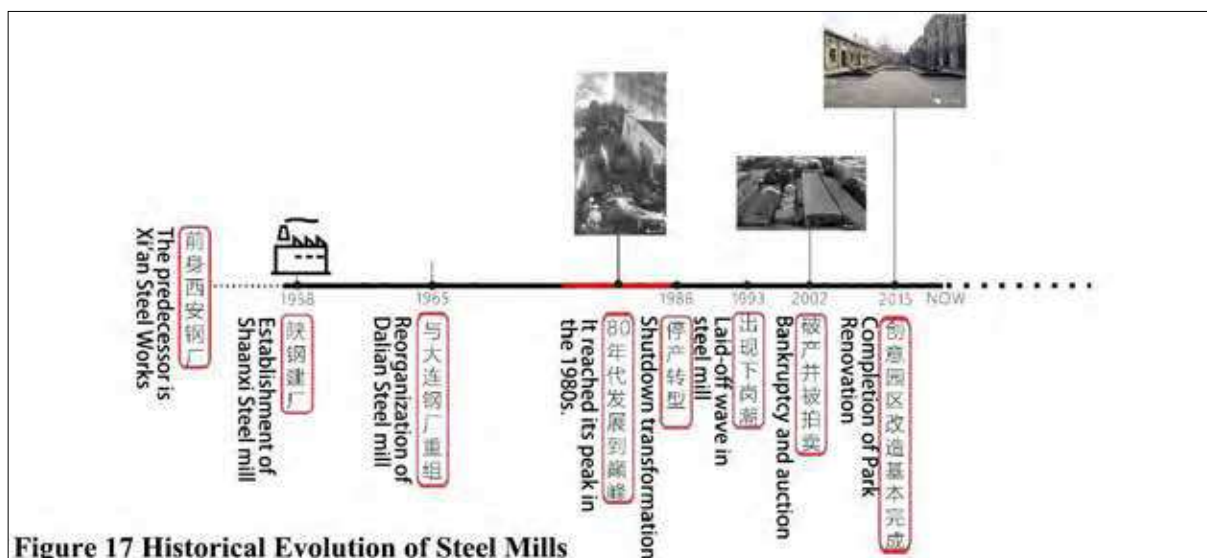

3.2. Memory factory

In the cities where we live today, changes are happening every day, and the speed of urban development and expansion is getting faster and faster. At the same time of demolition and construction, individual memory is perishable. But the city is not a museum, and we can not regard the city buildings as cultural relics to store and display. Industrial heritage is the embodiment of urban history. We hope to preserve the unnoticed architectural remains in the city and excavate the historical memory behind them.

The old steel mill is an industrial site, which carries a memory story of many people. But it was gradually forgotten, so we went to find the story behind the traces of the steel mill, designed to present these texts, let people read the past and present of the old steel mill.

3.2.1 Historical background

The creative park of Xi'an Old Steel mill, formerly Shaanxi Steel mill, was founded in 1958 and reorganized in Dalian Steel Works. It reached its peak in the 1980s and produced a variety of military special steels. But with the country's economic reform, productivity declined, insolvency, and a wave of laid-off. It was declared bankrupt in 2002 and acquired by Huaqing Group. After the acquisition, most of the land in the South was used for residential construction. The remaining land was set up in Huaqing College. The steel wire workshop in the original factory area was retained and transformed into today's creative park. As shown in Figure 17-18.

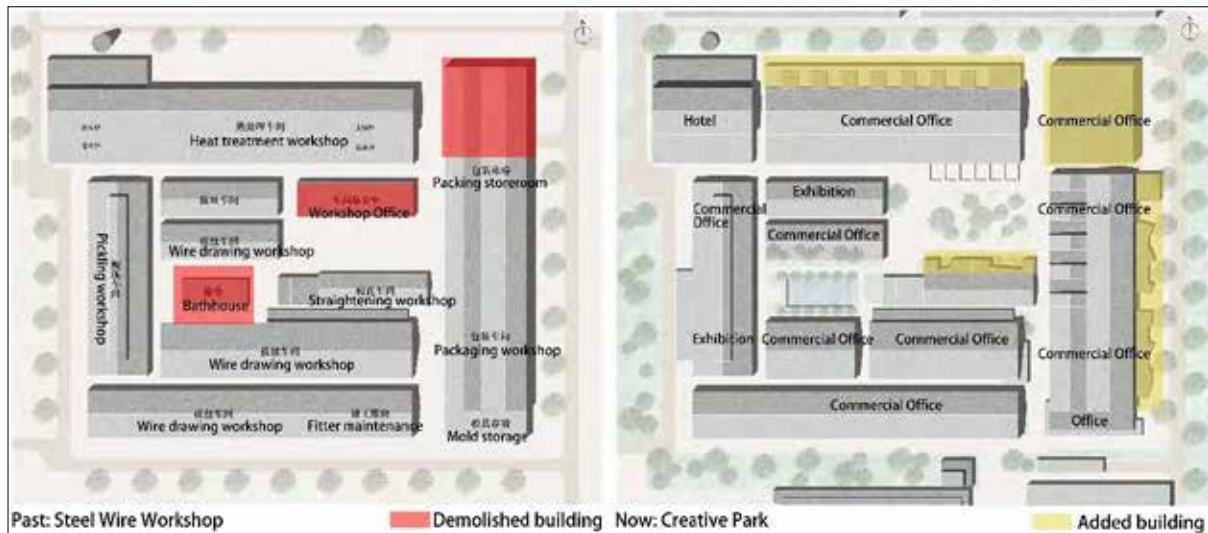

Figure 18 Contrast between the past and the present in steel mills

3.2.2 Elements of History and Reality

(i) Sites and events

For physical entities in the site: buildings, waste equipment, trees, and traces. These things are visible and tangible in the field. At the same time, collecting old photos, objects, newspapers, books, awards and so on, they all bear the memory of the times and individuals, which is what we need to present.

Figure 19 Sites and events

(ii) Traces

For these traces scattered in every corner of the steel plant, they all bear the memory of different people, but they are ignored by people. We have found 102 such traces, which have been endowed with texts through a large number of sociological surveys and interviews. The following figure is an example, as shown in Figure 20-21.

Heritage and people's real life are intertwined, and the memory they bear is easily forgotten by us. It is presented through text mining and subsequent design. Connecting the past memory with the reality, whether the memory itself or the object can be in the same memory field to dialogue with the historical heritage.

Figure 20 Traces and Text Examples

Figure 21 Traces and Text Examples

3.2.3 Design strategy

These traces are scattered in every corner of the steel plant and are particularly dispersed. Through the identification catalogue system, history and reality are connected in series, the red line identification system is used to connect and present the historical elements (as shown in Figure 21), and the yellow line identification system is used to connect the realistic elements (as shown in Figure 24).

Figure 21 Catalogue of Linear Identification of Historical Elements

Figure 22 Sample node design

Figure 23 Design and construction of joint as an example

Figure 24 Catalogue of Linear Identification of Realistic Elements

Figure 25 Design and construction of joint as an example

3.2.4 Brief summary

In the process of urban development, many things will be forgotten and discarded, along with the disappearance of our city's memory and emotions. Each individual has his or her own memories of the past. As time goes on, these memories will gradually disappear. Old steel mills used to be factories, with nearly 10,000 people working there. There were many people's memories and feelings. Later, more than half of the factories were demolished, and the remaining parts are now transformed into creative parks. Will Creative Parks continue to exist in the future? We don't know, but we hope to make these buildings warm and emotional by excavating historical memory, and provide others with a model or ideas to solve the disappearance of memory in urban change. Our generation does not forget the past generation, and the next generation will not throw us into the abyss of forgetfulness.

4. Conclusion

Memory superposition makes it easy for individual memory to produce more intersection and strengthen direct or indirect connection with this important historical memory. It is intended to express and strengthen this idea through such design. It is also a criticism of the traditional way of heritage protection to some extent.

From a critical point of view, first of all, we should talk about the recognition of heritage ontology. For the recognition of cultural heritage, professionals naturally need not say much about it. Through archaeological discoveries and long-term research, experts and scholars will have a more comprehensive and systematic understanding of it. However, the way non-professionals perceive cultural heritage will first be based on their own knowledge accumulation. People may have some

knowledge of important world cultural heritage. For most heritage sites, people are in a more embarrassing situation. There is a strong sense of distance between people and heritage, which is often caused by time and space. It is a pity for heritage protection that people will lack the interest to have more knowledge of it and the heritage itself is hard to be perceived.

Through the selection of individual memory and major historical memory, this paper analyses and interprets them from two aspects of theory and design, and on this basis, supplements the relevant ideas, methods and principles in heritage protection and display. The purpose of the design method is to explore a contemporary way and means to integrate historical information into people's lives and make it interwoven with people's lives. This is not only confined to architecture, urban planning or heritage conservation, but also should be interdisciplinary and multi-disciplinary. Under transformation of cultural heritage cognitive context, the emphasis on individual memory is intended to trigger the recognition and thinking of individual memory, and to connect and construct the relationship between individual and heritage through memory. In such a context, we recognize individual memory from the perspective of heritage protection. While the historical heritage is recognized, individual memory is superimposed to connect historical memory with human life.

Transforming Built Heritage and Landscapes

Emerging New Model of Urban Residential Historical Built-up Area Renewal in China: Five Practice of Urban Renewal in Shenzhen, Guangzhou and Shanghai

Long Jiayu, Liu Gang

College of Architecture and Urban Planning, Tongji University, longjiayu1994@gmail.com

College of Architecture and Urban Planning, Tongji University, liugang_tj@126.com

Abstract: China's urban development need to seek a new path, with the putting forward of inventory planning and the deepening understanding of heritage. In this context, a number of cities begin to explore new models of urban development based on the requirements of heritage protection and the demand of old district transformation. The problem is, are these new models balanced, harmonized and sustainable? Shenzhen, Guangzhou and Shanghai are all in the transition after the rapid urban development. "Urban village" in Shenzhen is a kind of old residential area derive from village bypassed by urbanization due to high cost. "The historic and cultural blocks" in Guangzhou face the dilemma stem from the original demolition model. "Lilong house block" shaped up in modernization as a type of grouped residential buildings in Shanghai, facing the high-intensity use. These three kinds of residential historical built-up areas are in urgent need of a new round of urban renewal. Based on this background, Shuiwei village and Yutian village in Shenzhen, Yongqing Lane in Guangzhou, Chunyangli and Chengxingli in Shanghai, these five historic residential built-up areas renewal project, with the goal of heritage protection, livelihood improvement and urban development, take the new models with multi-subject participation, urban space restoration, construction retention, and new functions placement. However, its occurrence mechanism, participants, and results are different due to its own characteristics and local urban renewal laws. This paper analyzes the advantages and limitations of these five models by comparing the background, the characteristics of the objects, the target positioning, the mechanism of occurrence, the operation mode, the results and follow-up works. Then study its rationality and adaptability, hope to provide a basis for the exploration of the future renewal mode of better residential historical blocks.

Keywords: urban renewal; built heritage; historic block; heritage protection

Introduction

With the development of social economy into a transitional period, the development of stocks and the continuous improvement of the sense of heritage protection in the whole society, the transformation of old urban areas in China began a comprehensive transition to organic renewal.

Under the new development background, the new renewal pattern is emerging in the recent history settlement renewal of Shenzhen, Guangzhou, Shanghai and other large cities. These modes are different from the freezing protection or the demolition and construction of new buildings with a high plot ratio, which were widely

adopted in China before. They try to form a comprehensive transformation mode by considering the improvement of people's livelihood, heritage protection and urban function development at the same time.

This paper is based on the question of whether these new development models are balanced, harmonizable and sustainable to meet the needs of value realization in a more diverse, broader and longer-term future urban renewal? As the core problem, through the investigation and analysis of five comprehensive renovation cases in Shenzhen, Guangzhou and Shanghai, this paper discusses the new model of protection and renewal of future residential historical built-up areas and puts forward policy suggestions. [Paragraph]

The Full Paper must be written in English within 11 pt Times New Roman. The text should be justified. The Full Paper including figures, tables and references must have a length of 3,000 and 7,000 words including abstract, figures, references and notes.

All accepted papers will be published in the online proceedings which will have an ISBN number and be made accessible from the conference website after the conference.

With the development of social economy into a transitional period, the development of stocks and the continuous improvement of the sense of heritage protection in the whole society, the transformation of old urban areas in China began a comprehensive transition to organic renewal.

Under the new development background, the new renewal pattern is emerging in the recent history settlement renewal of Shenzhen, Guangzhou, Shanghai and other large cities. These modes are different from the freezing protection or the demolition and construction of new buildings with a high plot ratio, which were widely adopted in China before. They try to form a comprehensive transformation mode by considering the improvement of people's livelihood, heritage protection and urban function development at the same time.

This paper is based on the question of whether these new development models are balanced, harmonizable and sustainable to meet the needs of value realization in a more diverse, broader and longer-term future urban renewal? As the core problem, through the investigation and analysis of five comprehensive renovation cases in Shenzhen, Guangzhou and Shanghai, this paper discusses the new model of protection and renewal of future residential historical built-up areas and puts forward policy suggestions.

1. The dilemma facing China's urban development

The development of Chinese cities begins to enter the stock development stage, which is the main reason for Chinese cities to seek a new mode of urban renewal from "demolishing old buildings and building new ones". As China's economy moves from the "old normal" of pursuing rapid economic growth and industrial-led manufacturing to the "new normal" of pursuing development quality, transformation of industrial structure and transformation of power mechanism. The urban construction of medium and large cities has also shifted from "incremental development" to "stock development". In the previous stage, because of high construction speed, low cost and high construction quantity request, a large number of construction projects can be in space or at low cost operation, in the history of proper such areas are usually distributed in the city, it led to the old city center in the construction of this round of neglected by the government or the development main body. This is reflected in the three cities of Shenzhen, Shanghai and Guangzhou as villages in the city, lilong blocks and historical street districts.

However, after the construction land available for rapid processing is gradually completed, it mainly relies on the fiscal revenue of land transfer fee, the increasingly serious livelihood situation of the old

areas, and the gradually improved sense of heritage protection, which makes the government have to face the problem of renewal and reconstruction of the residential historical built-up areas in the city center.

But these three types of residential historical built-up areas face different problems.

The urban villages in Shenzhen are faced with the problem of the distribution of benefits caused by collective ownership of land property villages. In Shenzhen, village in the city is a village surrounded or run by urban built-up areas within the scope of urban planning or on the edge of the city. Due to China's special land system, the property rights of all land in cities are owned by the state, while the property rights of land in villages are owned by village collectives. At the same time, urban community management is part of the work of the grass-roots government, which is under the unified management of the state, while village communities have certain autonomy, which is managed by the "villagers committee" as an autonomous organization. Therefore, the villagers have the right to distribute, earn and supervise the village collective as an economic organization. Therefore, villagers have the right to distribute, profit and supervise the village collective as an economic organization, which makes the land renewal in urban villages more complicated than other land in ownership.

The main problem of Shanghai lilong blocks is the contradiction between the demand of improving people's livelihood and the demand of feature protection. The lilong blockss in Shanghai were developed and built after Shanghai opened its port in the mid-19th century. It is a modern residential neighborhood with rich inner alleys, connected vertical buildings and high density. They have been largely dismantled in the subsequent rounds of large-scale urban construction, and gradually evolved into "group rental" residential communities with high use intensity, single living function and high population density in the public housing rationing and reform. At the same time, these living communities are faced with old houses, incomplete facilities, hidden safety problems and other living problems.

In Shanghai, lilong block, a lilong house originally designed as an 80-180 square meters house for one family, now is divided into several rooms for 5-8 families with an average area of less than 30 square meters. The more than half of the residential buildings in the lilong district, which were classified as "old-lilong" and closer to traditional Chinese houses, did not have modern sanitation. This was called "toilet problem" in Shanghai, and Shanghai urgently needed to renew lilong district, one of the reasons is the center of the people's livelihood problems in urban situation and international metropolis development goal, under the background of the Shanghai government proposed "before 2020 years, solve city's toilet problem" requirements, prompted the lilong blocks, especially given priority to with the old lilong blocks to search for new renewal mode.

In the last stage, the government's means to "eliminate toilets" was usually to expropriate the blocks, relocate the residents, and build new buildings by demolishing the old ones, which not only solved the problems of people's livelihood, but also benefited the land and urban development. However, in 2015, Shanghai announced the list of the first 119 landscape-protected neighborhoods, including a large number of lilong blocks. In 2017, the list of style protection neighborhoods was expanded, and some of the lilong blocks that have already been transferred to the agreement were covered, and emergency protection was carried out. This also made the original demolition and new construction, and greatly increased the floor area ratio to balance the high demolition costs. The method no longer applies, and

a new protection renewal model is imminent.

The same kind of rescue protection is happening in Guangzhou, where the main problem is the conflict between landscape protection and the development of the city center. In the old central city of Guangzhou, a large number of historical blocks are in the area. A large number of historical districts are located in the old central district of Guangzhou. In 2006, the Enning road district was identified as "contiguous dilapidated houses", which was initiated as the first old city reconstruction project and will be demolished and rebuilt. Under the impetus of the multilateral force, however, the "Guangzhou Historical and Cultural City Protection Plan" in 2007 included Enning road district into the "historical and cultural district", which made the citizens, planning units, developers and style protection work in the next few years. The interior has been saving the transformation mode of Enning road district, and Enning road district has also entered the "frozen" protection. Until 2014, the "Procedures for the Protection of Historic Buildings and Historic Preservation Areas in Guangzhou" was officially implemented, and the relevant regulations were also introduced one after another. In 2016, a micro-reform model suitable for historical urban areas was proposed, which enabled the Yongqing block project in Enning road district to begin. start up.

Generally speaking, when the development situation of Chinese cities changes, these three cities are looking for a new mode of protection and renewal that is suitable for them and can simultaneously realize the three major goals of heritage protection, people's livelihood improvement and urban development.

2. Case study of new protection and renewal mode -Shenzhen, Shanghai, Guangzhou

2.1. Shenzhen - Village in the City Renovation

2.1.1. Shenzhen Urban Renewal Regulation System

Because Shenzhen has a certain degree of autonomy as a special zone, it has its own particularity in the legal system. First of all, Shenzhen has implemented two core policies for its urban renewal work: the "Shenzhen Urban Renewal Measures" and the "Shenzhen Urban Renewal Measures Implementation Rules". In addition, three sets of supporting measures have been issued, namely, "Practice Guidelines", "Special Provisions" and "Interim Measures". "Practice Guidelines" provide guidance for specific practices at various stages of urban renewal, such as guidelines for planning declaration, planning approval rules, technical provisions for planning preparation, etc. The "special provisions" include the recommendation provisions for guaranteed housing, the provisions for innovative industrial accessories, and the measures for the identification of old houses, as well as the provisions on the identification of objects and the requirements for allocation and construction. "Temporary measures" are mainly used to solve the dynamic problems constantly encountered in urban renewal. Two core policies and three sets of supporting regulations jointly guide the specific mode development of Shenzhen urban renewal.

2.1.2. Shenzhen Urban Renewal Basic Modes

There are two basic modes of urban renewal in shenzhen: demolition and reconstruction, and comprehensive renovation.

The urban renewal mode of demolition and reconstruction demolish existing buildings, change the nature of land use, the main body of rights, and the period of use for re-planning. This model mainly meets the needs of urban development, with the "propose urban renewal unit plan—the preparation of urban renewal unit planning—confirmation of the implementation body—land transfer—project construction and construction” as the control process, is similar to ordinary urban construction process, the difference is put forward the concept of "urban renewal unit" as an object to pattern implementation. "Urban renewal unit" mainly refers to the built land with the land area of more than 3000 square meters, the construction quality has serious safety hidden danger, the existing use after the function positioning adjustment does not conform to the planned function, the industry has serious pollution or land use. Different from the general urban construction process, in terms of confirming the implementing bodies, the urban renewal unit demolition and reconstruction project in Shenzhen accepts multiple rights subjects to join or set up a company, and the implementing bodies sign renovation cooperation agreements with village collective economic organizations and units to implement urban renewal cooperatively. This is actually a response to the urban village in Shenzhen, as a unique "residential historical built-up area with collective land ownership" among the three cities.

In this model, there are five main innovation points: first, urban cooperation, hierarchical preparation of five years of special planning, and the definition and implementation of the target strategy and update indicators. The second is to establish a city renewal unit planning system, so that it has the same legal effect as the control detailed planning, reaching the depth of the constructive detailed planning, which is equivalent to separately setting a public interest priority and public participation negotiation for each urban renewal unit. Controlled detailed planning. Third, the government guides and plays a decisive role in the allocation of land resources. The rights subject can implement the urban renewal project by itself, and the market entities can also be implemented separately or jointly. Fourth, innovate the land management policy. The land for reconstruction can be transferred by agreement to the original right holders or market players participating in the reconstruction, and establish different land price standards. The fifth is to emphasize the support for the construction of housing, public facilities and innovative industrial buildings.

The comprehensive rectification urban renewal projects mainly include improvement of fire facilities, infrastructure and public service facilities, improvement of street facades, environmental remediation and energy-saving renovation of existing buildings. Additional facilities can be added as needed and required. The main body of implementation of this update mode is the government department, and the funds are mainly borne by the government, and some of them are borne by the relevant obligee through consultation with the district government. However, the problem with such urban renewal is that external environmental remediation does not solve the fundamental problem, and financial investment is not sustainable.

On the basis of this model, in 2017, Shenzhen issued a "Shenzhen Housing Leasing Pilot Work Plan” and other documents to emphasize the requirements for pilots of large-scale leasing houses through the comprehensive rectification of urban villages, and to provide supporting master plans at the municipal level.

2.1.3. Comprehensive Rectification - Shuiwei Village, Futian District, Shenzhen

Shuiwei village, futian district, shenzhen is a typical case of comprehensive renovation mode. The linneng talent apartment transformed into the first talent security housing community in shenzhen transformed from an urban village. With a planned area of 8,000 square meters, 29 self-built houses of villagers are transformed into 504 talent apartments. In space, it has mainly done some remediation work, including rectifying the external environment and transforming the internal space. The fire protection, municipal supporting facilities, additional elevators and air public corridors were added, and the original urban texture, spatial scale and architectural structure were preserved. The function is mainly residential and commercial, with the commercial space below the third floor, and the above as talent apartments into the policy-supported housing system.

A typical multi-subject participation in the urban renewal project: the Futian District Government initiated and led the Shuiwei Industrial Co., Ltd., which was established on behalf of the villagers' collectives, to negotiate with the property leasing, and the government delegated the market. Shenye Land Investment Development Co., Ltd. is responsible for the renovation and operation of the talent apartment. Shuiwei Industrial Park Co., Ltd. and Shenzhen Commercial Investment Co., Ltd. jointly established Shuiwei 1368 Street Commercial Management Co., Ltd., which is responsible for the commercial space below the third floor. Reconstruction and operation; Futian District Housing and Construction Bureau will lease back the restructured property and distribute the talents of the enterprise. Under this mode of operation, the government has achieved the goal of improving the people's livelihood and improving the urban space efficiency with a subsidy of 30 million yuan and a subsidy of 75 yuan per square meter per month. Shenye Land Company passed the transformation investment of 3,000 yuan per square meter, and its operating expenses for 8 years, got the rental income of 75 yuan per square meter per month, the operation experience of the redevelopment of the urban housing rental project and the subsequent lease priority right. The village collective obtained a monthly rental income of 475 yuan per square meter, 30 million yuan start-up funds for infrastructure and environmental improvement, and the appreciation of community properties. According to the current situation, in this urban renewal project, the government makes multiple subjects obtain the required benefits with less capital input cost, benefiting from the clarity of appeals of all parties, the establishment of the platform of rights subjects and the transformation of spatial rights and economic rights.

2.1.4. Comprehensive Rectification - Yutian Village, Futian District, Shenzhen

Yutian Village, Futian District, Shenzhen covers an area of 17,200 square meters and was launched in September 2017. It is the first stop for Vanke to launch the "Million Village Recovery Plan". Vanke will carry out the project operation in the way of obtaining the lease right of the self-built houses of the villagers and putting them into operation. The mode is mainly for the comprehensive rectification and content operation of the village in the city. The former is mainly to improve the living environment and supporting services. The latter includes the introduction and management of housing properties, as well as the introduction of other industrial chains such as commerce, industry, and education, and profitability through long-term operations.

The main implementation body of this project is Shenzhen Vanke Group, which initiated the project plan, and its Wancun Group contacted the villagers' owners, arranged a series of work such as property acquisition, renovation and reconstruction, operation and management, and other teams such as its park house group carried out follow-up management and operation. One of the reasons why Vanke initiated the project is that the enterprise has the need for transformation in the new urban development environment. Therefore, it exchanges the investment of comprehensive rectification and the cost of property group and operation management for stable rental income and profit of other industries in the later stage and finally achieves the long-term profit goal from the short-term balance of income and expenses. In the process, the villagers increased the value of assets and obtained stable capital gains.

2.2. Shanghai - Shikumen Lilong Comprehensive Reconstruction

2.2.1. Shanghai Urban Renewal Policy

After experiencing the last round of efficiency-based renovation of the old city, Shanghai issued the "Measures for the Implementation of Urban Renewal in Shanghai" in 2015, targeting "the transformation of old districts, the transformation of industrial land, and the transformation of urban villages that have been approved by the municipal government". The region has formed a new urban renewal regulation system with this as the core, and formed supporting documents related to land planning such as the "Shanghai Urban Renewal Planning Land Implementation Rules" and the "Shanghai Urban Renewal Regional Assessment Report Results Standards". In the implementation of urban renewal, planning adjustment, land, construction management, powers and other aspects, as well as the "Shanghai Municipal Housing Comprehensive Transformation Management Measures" and other comprehensive transformation and management of urban housing. At the same time, there are also the "Regulations on the Protection of Shanghai's Historical and Cultural Areas and Excellent Historical Buildings", which stipulates the principles of transformation, the contents of transformation, the management institutions, and the specific implementation procedures and related technical requirements.

2.2.2. Shanghai Urban Renewal Modes

There are three existing renewal modes in Shanghai: old district reconstruction, housing transformation, and development and adjustment of historically remaining Maodi. The main point of the old district reconstruction model is "leaving houses without people", mainly for the scope of the old district reconstruction, planning to determine the areas that need to be sliced or partially protected and functionally updated, and the land reserve can be implemented through "levy without dismantling" "expropriation without demolition" or self-raised funds from diversified subjects can be introduced to organize the implementation of feature protection and renewal. Its problem is that the investment demand is too large, the new function has limited ability to digest, as most of the existing cases are transformed into commercial blocks. The core of the complete set of housing transformation is "retaining the house and retaining the people", mainly for the public housing that is determined by the plan to protect reservations. The government invests in adding supporting facilities and infrastructure, retains the original use function, and removes part of the lease relationship. Carry out a

complete set of renovations to improve the living environment of residents. The problem with this model is that it can only improve the living conditions of residents in a limited way. However, the updated land is easy to fall into the hardening state, and it is difficult to wait for the second round of upgrading, and it will decay again as time goes by and become the problem area of the city. The last model is aimed at "Maodi" which means projects that the government signed agreements with the developers before the requirements for the protection of the city heritage and for various reasons, there projects has been no levy and construct for collection and construction. For such objects, if it is determined that it is necessary to implement the protection of the heritage, the planning and land use demands needs to be update according to landscape protection. However, the problem is that when the land transfer contract is signed, the amount of new construction promised by the government to the developer cannot be realized today. There is a big contradiction between development and city heritage protection. All of the above three models were born to meet the requirements of landscape protection requirements and stock development, but they all have difficult problems to solve, and it is difficult to fully estimate people's livelihood, city heritage protection and urban development.

2.2.3. Housing Transformation - Chunyangli, Hongkou District

Chunyangli is located in Tilanqiao Street, Hongkou District, Shanghai, with a total construction area of 20,762.55 square meters, all of which are public houses and are affiliated to Hongfang Group. In 2015, it was listed as a historic conservation block. By 2016, the difficulty of demolishing a large number of illegal buildings forced Chunyangli to carry out an overall transformation. The Chunyangli renovation project keeps all the households on the people; removes the illegal buildings, protects the buildings by dismantling the old buildings and rebuilt them, each house has an independent entrance and independent kitchen and bathroom facilities, The situation of original multi-family residents live together in a set of lilong house, use a public entrance, and no kitchen and bathroom facilities, shifted to "household sets". One of the different points of the Chunyangli renovation project is that it was initiated by the Tilanqiao Sub-district Office. In cooperation with the Hongfang Group, the Hongkou District Housing Management Department allocated special repair funds to transform 1,181 households with 280 million yuan.

Except for the capital investment, the government's greater investment in the Chunyangli project is the labor cost of the grassroots workers in the Sub-district Office, which in exchange for the improvement of the environment, the protection of the historic buildings and the improvement of the people's livelihood. And after the transforming, these houses through the By the rental company to solve community problems and promote community development. Residents lost some illegally built space, but they received independent kitchen and bathroom facilities and 3-5 square meters area. At the same time, the overall environmental improvement also brought them an increase in the value of the property.

2.2.4. Complete set of transformation - Chengxingli, Huangpu District

No. 8 Block (Chengxingli) in Huangpu District is located in Huanghe Road, Huangpu District,

Shanghai. It belongs to the historic conservation blocks of Shanghai. There are many new lilong and old Shikumen lilong buildings in the square, and the overall texture is complete and orderly. The buildings involved in the renovation pilot are all public houses and old lilong. The project was initiated by the Huangpu District Housing Security and Housing Administration. It was implemented by the Nanjing East Road Sub-district Office and Huangpu Land (Group) Co., Ltd., based on the principle of comprehensive repair, environmental improvement and balanced improvement. Each household is equipped with an independent kitchen sanitation facility while dismantling the illegal construction. Different from Chunyangli, Chengxingli signed a comprehensive transformation agreement for the residents involved in the transformation, and carried out comprehensive environmental improvement and overall comprehensive transformation. At the same time, it signed a lease relationship cancellation agreement with some public housing tenants to release the space to achieve the configuration of independent kitchen, this kind of means is called "subduct households". Which part would be subduct is initially identified by the design plan. The part that terminates the lease relationship is preliminarily determined by the design plan. In the design plan, the parts that are not involved in the transformation and cannot be completely restored can also be voluntarily applied for and considered by the project evaluation group. If the extracted area is not up to the standard, the public signing and soliciting can be conducted. Finally, the lessee who dissolves the lease relationship shall be compensated with one-time monetary compensation.

2.3. Guangzhou - Historic District Renewal

2.3.1. Guangzhou City Renewal Policy

The core of Guangzhou's urban renewal policy system is the "Guangzhou Urban Renewal Measures" promulgated in 2015. On the basis of government control, it strengthens the participation of multiple entities, explores various ways and means of "micro-reform", and pursues comprehensive benefits. Around this core are three implementation methods for different objects, "Guangzhou Old Town Renewal Implementation Measures", "Guangzhou Old Factory Renewal Implementation Measures", and "Guangzhou Old Village Renewal Implementation Measures". In the relevant government agencies, it established the Urban Renewal Bureau in 2015, mainly to formulate policies and regulations, research on innovative methods and organize implementation.

In terms of planning and control, it is divided into three levels: "Guangzhou 'Three Kinds of Old Area' Reconstruction Planning Outline" clearly defines the transformation principles and basic strategies from the overall level, and connects with the overall urban planning, and is responsible for the macroscopic grasp. The three special renovation plans for the old city, the old village and the old factory are controlled from the middle level. In the micro implementation, the transformation plans and guidelines for each plot are included in the control system and form a statutory plan.

There are two basic models for urban renewal in Guangzhou: comprehensive renovation and micro-reconstruction. The comprehensive transformation means the renewal mode based on demolition and reconstruction. The micro-reconstruction refers to the partial demolition and construction of buildings, the replacement of building functions, the maintenance of repairs, and the improvement, protection and activation of the rectification under the premise of maintaining the current construction pattern,

improve the implementation of infrastructure and other methods of implementation. The comprehensive transformation is similar to the demolition and old construction model in Shenzhen, in most cases, the property rights are integrated and belong to the new ownership, the compensation for demolition compensation is large, the investment is large, and the return period is long. However, the new micro-transformation mode enables property right unchanged or collective land to be transferred to state-owned land by paying land transfer fee paid, so as to achieve faster results at a lower negotiation cost and less investment. The transformation mode mainly includes partial demolition and reconstruction, functional replacement, renovation and renovation, and protection and activation.

There is no urban renewal unit in guangzhou, but it adopts the method of "one district, one policy" and takes the historical protection blocks as the unit to transfer the land with conditions, while the historical blocks that are not qualified for transfer are leased. Appropriate attention to the preservation of social and cultural diversity while maintaining the integrity of public facilities and community restructuring while appropriately retaining indigenous peoples. In terms of mechanism, Guangzhou has established a public-private partnership mechanism to set up a construction management committee for the renewal of the community to promote communication and cooperation between the government, developers and society. At the same time, actively introduce market forces to reduce the financial burden. In terms of policies, they explore the phased settlement and small-scale land transfer policies, appropriately support market-oriented behaviors, and consider the mix of functions. At the same time, we will introduce special policies for the renovation of old communities.

2.3.2. Micro-reconstruction - Yongqingfang, Enning Road, Liwan District

Yongqingfang is located in Enning Road Block. Enning Road is the longest arcade-house street in Guangzhou. It was called "the most beautiful old street in Guangzhou". It was built in 1931 and started to be demolished in 2007. However, due to strong social reaction, the progress was slow down. In 2010 the government decided to set up a historical and cultural protection block. In 2012, the "Guangzhou Historical and Cultural City Protection Plan" was completed, forming a superior protection plan. Due to the shelving of the project, until 2016, the neighborhood environment was deteriorating and forced to "freeze protection". In 2016, the pilot project of 8,000 square meters of micro-reconstruction of Yongqingfang was started, which was completed in 2017, and the second phase of the next year started the tender. There are three main development problems facing Enning Road Block: First, land use cannot be completed, and land acquisition and auction cannot be carried out. Second, for the physical space, the environment of the block has become seriously aging because part of residents has removed, and the phenomenon of moving back and continued renting has begun to occur. Third, on social appeals, the demands for improvement of people's livelihood and historical protection are equally strong, which makes the work stalemate.

"Yongqingfang", as the pilot project of the old city micro-reconstruction project in Guangzhou, won the bid by Vanke Group. The space strategy follows the principle of "repairing the old as the old" and implement on the base of retains the original street texture, respecting history and protecting the old city. In terms of functions and formats, the creative and entrepreneurial industrial park with Shared office space, including mass innovation office, education camp, living facilities and other industries. The long-rent apartment (Bo Yu) originally planned is integrated into the second phase of the project.

The social mechanism is centered on "government-led, enterprise-based, and residents' participation". Innovative leasing, bidding and auction--abandoning land bidding and auction, renting and selling, introducing content operators; introducing "build-operate-transfer" BOT Models – reduce government investment, attract social capital to build operations, and transfer 15 years later; encourage social participation – encourage encourage the individual owners who have not moved to update themselves or cooperate with operating entities to update. These three policies enable the unrelocated indigenous people and liwan district urban renewal bureau, which has acquired and stored the relocated property right, to lease the property to vanke company for unified transformation operation and leasing, thus solving the problem of property right decentralization caused by the stalled demolition process.

In terms of input and cost, the government paid early relocation costs, and obtained benefits such as improving people's livelihood, improving the historical and cultural district environment, long-term rental income after 15 years, and property rights of high-quality assets. Meanwhile, vanke invested 100 million yuan of reconstruction fund in exchange for basic balance of income and expenditure within 15 years of operation, brand marketing power brought by important cultural projects, experience advantage of the second phase project, priority lease right after 15 years, and brand growth benefits from establishing cooperative partnership with the government. Among the residents, those who move out get compensation income or rent income, while those who don't move out get the overall improvement of infrastructure and material environment.

3. Problem Remains and Suggestions for Future Protection and Renewal of New Model Development

Shenzhen, Shanghai and Guangzhou, as China's three mega cities, share the same four urban development needs: inheriting historical features, protecting cultural memory; promoting community development and ensuring improvement of people's livelihood; developing leasing business, helping housing supply reform; introducing innovative talents, improve the city's core competitiveness. Under such urban development needs, urban construction must shift to the development of stocks. The renewal model and corresponding institutional mechanisms of residential-type historical built-up areas located in urban centers are also undergoing transformation.

For Shenzhen, the comprehensive rectification of the villages in the city has shifted from the external environment rectification to the internal space transformation and functional adjustment, trying to solve the problem of "treating the symptoms and not treating the problem", but the standard system has not yet been established. It is necessary to combine relevant standards and the characteristics of urban village space to provide supporting policies as soon as possible in terms of fire safety, supporting facilities, relocation and resettlement and interest compensation, and clarify planning objectives and demands. At the same time, the supervision measures of the urban village leasing market need to be improved. The implementation of the renovation and upgrading has raised the value of property assets. The fierce market competition may lead to a rapid increase in rents. Relevant departments should strengthen supervision and curb violations and speculation. Meanwhile, it still has the problem of complicated planning and approval procedures. In the future, it should strengthen the cooperation among various entities, simplify the examination and approval procedures, and improve efficiency.

For Shanghai, there is no clear support and encouragement policy at the policy-level level, and the approval process is complex and strict, and it is difficult to make mistakes. The grassroots government is prone to fear and lack of courage to break through, make the pilot is difficult to carry out. In order to avoid policy obstacles and apply housing repairs; the planning and approval procedures are complicated, and the lack of public space and facilities in the residential-style historical districts has not been alleviated; the "subduct households" are extremely difficult, but if the "subduct households" can not be implemented, the problem of tight living space still exists; the implementation model is not promoted and sustainable, and long-term operation mechanism and management model have not been found; at the same time, lack of special fund support (especially start-up funds) and investment channels, the objective difficulty of updating and transformation is high; profit model and fund balancing mechanism design is lacked.

For Guangzhou, the core problem to be solved is the policy: the planning policy and the management caliber are not clear. At present, the implementation of urban renewal projects is trying to avoid policy obstacles and apply for housing repairs. The policy of small-scale land use transfer is also insufficient, which greatly limits the land use potential of the updated project and the potential for renewal. In terms of implementation management, there is a lack of control and standards for the adjustment and balance of functional formats. Firstly, there is no policy support to convert some residents to non-residents, which is in the gray area. Meanwhile, the transformation project has the tendency of excessive commercialization, which has a certain impact on community living.

Finally, after sorting out the emerging renewal modes of the three cities, we put forward development suggestions for the future protection and renewal modes of the historical built-up areas in Chinese cities, starting from development regulation policy, guidance of social capital, optimization of mechanism mode and emphasis on social governance.

In terms of land regulation policies and mechanism models, we should first make clear the standards, base on the improvement of people's livelihood, make clear how to retain historic building, and deepen the screening of historical building reservation, replacement and demolition. At the same time, the comprehensive transformation requirements and supporting facilities standards should be clarified. Combined with relevant standards and the spatial characteristics of residential historical blocks, the target indicators of eliminating safety risks and improving supporting facilities should be clarified. Then, it is necessary to simplify the program approval process, promote the self-organization of grassroots governments or residents' organizations to provide programs, approve by district governments, and the overall planning and implement by sub-district office.

In terms of capital introduction, public resources and social capital should be introduced, the financial subsidy system should be improved, special support fund policies should be issued, and the market should supervise the follow-up operation.

Most importantly, in the future, we need to explore a more balanced, coordinated and sustainable organic renewal model based on four approaches: multi-player cooperation, balance of economic interests, spatial transformation and functional adjustment.

Paradoxes of the Italian Historic Centres between Underutilisation and Planning Policies for Sustainability

Abstract: The paper presents the analysis of the statistical data on population and real estate in 20 small-to-medium-sized cities in Northern Italy and shows a high rate of vacancy of housing and significant shrinkage of businesses and institutions in the historic centres, where urban heritage is concentrated. Given these findings, the paper analyses the official city plans of the cities with the worst underutilisation conditions, to understand how the plans have reacted to the decline of the centre. The result shows the extensive planning and regulation activity has very limitedly registered the phenomenon and failed to propose the empty inner cores as resources to reduce land consumption and recycle valuable assets in a circular economic vision. Combining the statistical data and the findings from the city plans, the paper concludes that Italian historic centres are living paradoxes—a collection of beauty, icon of well-being, model of sustainability, but abandoned—and therefore, the dense regulatory mechanisms that were necessary to conserve urban heritage during the decades of economic and demographic growth must be reframed to implement a circular economy and adapt to new requirements for living conditions.

Keywords: urban heritage; historic centre; regulation; sustainability; city plan

1. Introduction and Research Method

Historic centres are the identity and heritage of Italian cities and have for decades been at the centre of cultural debate and administrative action, leading to extensive regulation activities and planning documents to conserve and restore them [1–9]. However, the interpretation of demographic movements and dynamics of uses over the past 30 years suggest that the effects of the planning policies and regulations on the settlement choices should be questioned because the internationally recognized heritage of the centres, one of the most valuable assets in urban Italy, is underutilized and therefore, devitalized and wasted. The issue of the underutilisation of the historic centres has not been studied in detail considering the long time span yet, even though the survey of the Associazione Nazionale Centri Storici Artistici has greatly contributed [10], its relation with plans and regulations have not been analysed; some literature deals with the problem of the regeneration of the historic centres [11–14], but none deals specifically with the reaction of planning instruments to underutilisation and little public discussion debates it. The research presented tries to fill this void and is the second phase of an on-going investigation.

The first phase of the research analyzed the Census data of 1991–2011 of demographic movements and property dynamics of 14 small-to-medium-sized cities in Northern Italy [15,16]. The findings show severe underutilisation in the city centres and urge to question the effectiveness of the planning approach and regulations. The research method of the second phase involved the following steps:

- We increased the number of cities we investigated to 20 in order to cover the whole of Northern Italy; the same phenomena found in the first 14 cases were found also in the six new ones.
- Selection of the cities to further analyze according to the findings: The cities with the worst condition of vacancy were selected because the phenomenon in these cities is so evident that local planning activity should have tried to deal with the issue; the paper claims the city plans are not the main factor which caused the vacancy, but a mix of socio-economic causes. Therefore, the paper explores how planning activity reacts to the phenomenon where it is most observable.
- Collection of the city plans available in the official web page of the municipalities: The general planning documents and those specifically related to heritage conservation (if any) were collected.
- Analysis of the texts and maps of the plans, both in the descriptive parts (focusing on which phenomena are impacting the city according to the documents and if underutilisation is recorded among them) and in the design part (focusing on what development is proposed, what importance is given to sustainability, which actions are defined for the city centre and what role it is given in the future of the city). The selected cities are in different regions, and every region in Italy has a city planning law. Therefore, the planning processes are slightly different and the documents cannot be directly compared.
- Assessment of the conceptual and practical link between the phenomena of underutilisation and the choices of the plans for sustainability, that is to say if and how the “empty” built heritage in historic city centres is given a role to support the sustainable development of cities in the perspective of a circular economy and according to the International Charters and debate about urban development, which widely promote the connection of built urban heritage and sustainability [17–19].
- Conclusions, both expressed as paradoxes and challenges.

The structure of the paper is as follows: The second paragraph presents the results of the quantitative research about the underutilisation of the building stocks in the historic centres of small-to-medium-sized cities in Northern Italy between 1991 and 2011; the third paragraph presents the results of the qualitative research regarding the planning instruments, which define the future development of the city. The fourth paragraph introduces some paradoxes of the historic city centres, that is to say, the essential characters which should determine the value of the historic core, but fail to do so; these paradoxes should be the starting point for the re-framing of the cultural approach and the policies for the urban heritage, which is proposed in the last paragraph.

Cases of gradual decline over the last 20 years of the historic city centres in small-to-medium-sized cities can be found in the whole of Europe: Shrinkage in population, underutilized stock and diminished importance as places of exchange and congregation are widespread phenomena [20–24]. This paper wants to contribute to the academic and professional debate about this decline presenting the North Italian case, which is relevant because of the great value of its urban heritage, the extensive protection measures applied since the 1960s and it is a place where even centres enlisted in the United Nations Educational, Scientific and Cultural Organization (UNESCO) world heritage are underutilized.

2. Evidence of Underutilisation of the Built Stock in Historic Centres of Small-to-Medium-Sized Cities in Northern Italy

The research analyzed the Italian Census data from 1991 to 2011, the last comprehensive available one, of 20 small-to-medium-sized cities in six regions of Northern Italy: Friuli Venezia Giulia, Veneto, Trentino Alto Adige, Emilia Romagna, Lombardia, Piemonte [15,16]. There is no official classification in Italy of what a small-to-medium-sized city is; the research adopted the range between 30,000 and 200,000 inhabitants, which is pertinent to the dimension of the urban centres in Italy [25–27].

The analyzed cities are Udine, Pordenone, Treviso, Vicenza, Conegliano, Bassano del Grappa, Ravenna, Ferrara, Parma, Modena, Brescia, Mantua, Cremona, Bergamo, Pavia, Trento, Rovereto, Novara, Alba, Alessandria. All their city centres conserve a built heritage of exceptional value, some of them – Vicenza, Mantua, Ferrara – are listed as historic centres in the UNESCO World Heritage

Sites, while some others—Modena, Pavia, Ravenna—have monuments included in the same list. The analyzed cities are a very relevant sample of the urban world of Northern Italy and host almost two million people of whom almost 10% lived in the historic centres in 2011, see Figure 1, Table 1).

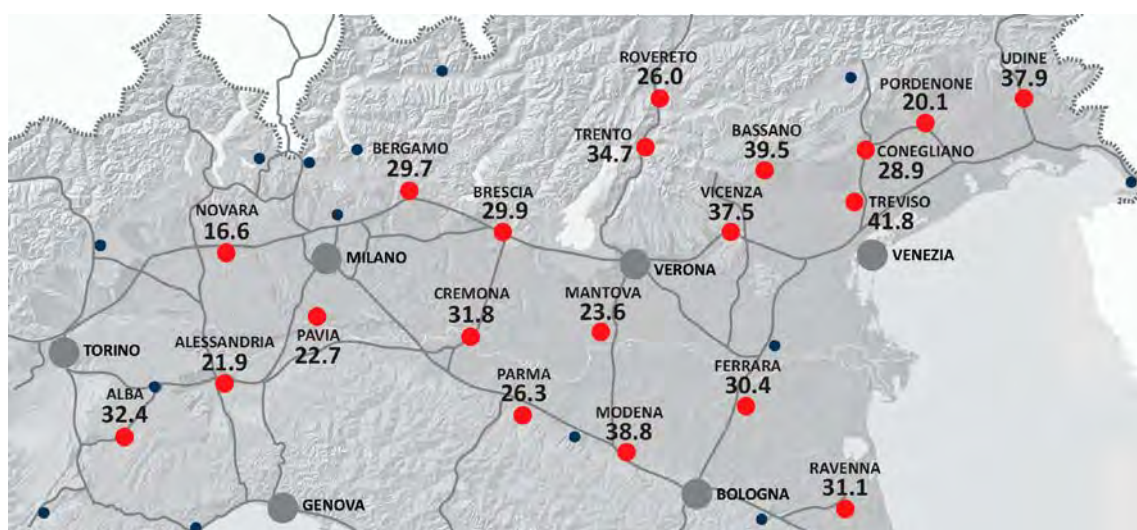

Figure 1. The 20 cities in Northern Italy; the numbers are the percentage of housing units not occupied in the ZTL.

The municipal territory of every city was divided into three areas to obtain specific results and compare dynamics: The inner part of the historic centre identified as the controlled traffic zone (ZTL), the rest of the historic centre defined by the last defensive walls and the rest of the municipality.

The analysis shows unoccupied housing (labelled “abitazioni vuote” by the Census) in the entire historic centre increased on average from 16% to 26% and systematically exceeded the other urban areas where the share of the unoccupied stock increased from 9% to 14.2%. The situation is even more significant in the ZTL: In these areas, the percentage of unoccupied housing increased from 18.8% to 30%.

The vacancy rate in ZTL increases significantly in some cities, such as Udine, Treviso and Modena when compared to the rate of the other historic centres; in Treviso, for example, from 1991 to 2011, the percentage of unoccupied housing reached 41.8%, whereas it was 21.4% twenty years previously. The vacancy does not appear to be related to specific parts of the historic centre but appears to be a widespread process; in fact, in the majority of the centres it does not involve buildings in their entirety and this partial utilisation mitigates the perception of the phenomenon.

The vacancy rate, moreover, does not relate to the degradation of built stock nor is the decline of the population due to neglect: The large majority of buildings in northern Italian city centres, especially those whose heritage is particularly valuable, were largely restored and renovated in the 1980s and 1990s, as were the large majority of public open spaces; therefore, they are an available stock in acceptable conditions.

The value of these empty units has an absolute economic significance; in fact, the sum is 33,775 units out of a total of 130,084 in 2011, with an increase of 17,642 units since 1991. If this empty stock is assigned an under-estimated value of 1000 euros/sqm and an average surface of 100 m² – the average size resulting from the analysis the Census Data for the 20 city centres – it sums up to a value of 3.37 billion euros, 0.2% of the Italian GDP in 2011.

Table 1. Synoptic table of some results from the Census data analysis.

City	Region	Population Outside the Center, 2011	Population Variation 1991-2011 Outside the Center (%)	Population Variation 1991-2011 in the ZTL (%)	Population Variation 1991-2011 in the Historic Center (%)	Unoccupied Units Outside the Center, 2011 (%)	Unoccupied Units Outside the Center, 1991 (%)	Unoccupied Units in the ZTL, 2011 (%)	Unoccupied Units in the ZTL, 1991 (%)	Unoccupied Units in the Historic Center, 2011	Difference 2011-1991 of Unoccupied Units Outside the Center (%)	Difference 2011-1991 of Unoccupied Units in the ZTL (%)	Foreigners in the Center on the Total Residents (%)

Notes: The cities selected for the analysis of the city plan are highlighted.

In the 20 centres that were analyzed, the population is decreasing: -20.118 units since 1991, on average -10.35%, but exceeds -20% in Ferrara and Bergamo. This decrease is not directly proportional to the percentage of housing vacancy, and is clearly less relevant; this difference may be related to the deaths of single elderly people who often live in the historic centres and the arrival of foreigners. In fact, despite being almost irrelevant at the beginning of the 1990s, in twenty years, foreign residents have become a significant percentage of the inhabitants of the oldest parts of the city – in Brescia, foreign residents exceed a 24% share of the population, in Modena this share reaches 26% – with an increase of twenty times compared to the figures of the early 1990s.

The abandonment concerns not only residential units but also companies and institutions. The results regarding the companies operating in the historic centres are not homogeneous among the 20 cases and, very often, companies have not decreased in number, but have been re-organized with a significant reduction in employees, decreased by between one-fourth and one-fifth when compared to 1991, with an average decrease of over twenty percentage points (-20.1%).

The results regarding institutions in the historic centres are more clear-cut. The density of institutions in the historic centre – the units per hectare – continues to be higher than in the rest of the municipality, but has suffered a drastic shrinkage, decreasing between two-thirds and four-fifths compared to 1991. The variation in institutions is homogeneous and indifferent to the regional location and the total local units declined by more than 70% (-73.9%) in the twenty years considered. Similarly, the institutions' employees decreased in all cases, with an average reduction of one-third. The average decrease in the rest of the municipal territories is also important, but minor: -58.3% for the local units. This diminution is partly due to the rationalization of office premises following mergers and partly due to relocation in more accessible areas of the city.

The interpretation of demographic movements and property dynamics of the last thirty years in 20 small-to-medium-sized cities in the whole of Northern Italy reveals severe underutilization; original inhabitants have been abandoning the centres, partially substituted by immigrants, enterprises are significantly reduced, and many institutions have opted for new locations. The choice of new locations by households, public institutions and businesses is exceptional as well as paradoxical because the abandonment involves parts of the city that have most benefited from the community's resources for centuries, constantly improving infrastructures and public spaces both in the quality of service and beauty.

3. The Missed Opportunity of Promoting the Re-cycling of the City Centres in the City Planning Instruments

Has the city planning activity considered the underutilisation of the cores? Has it considered it as a problem? The theme is central for the development of Italian cities in this period of urban reuse, when a circular economy and sustainability concepts should be considered. In fact, if the cities' agenda takes on a more rational use of the land through the careful selection of projects which consume land, in particular, affecting the primary sector where there is a concern about food production, and if the regeneration of properties through physical as well as social redevelopment is considered a priority, then the historic centre of Italian cities becomes a fundamental test of adapting a stock of primary cultural, economic and social value to contemporary needs and wishes.

Even though precise numbers for a large sample of cities had not been produced until very recently [10,15,16], the abandonment of the historic centre has been perceivable for several years in Italy. Therefore, it is plausible to hypothesize city planning documents have registered it and proposed to recycle the empty stock, adopting a circular economy approach, which integrates sustainable production as well as better use of resources. To understand the reaction to the phenomenon, the research explored the city planning documents of the cities with the worst condition of not-occupied units in the most valuable part of the city, the ZTLs. The paper claims the city plans are not the main factor which caused the underutilisation, but that it was a mixture of socio-economic causes, see paragraph 4.4 and Conclusions. Therefore, the paper explores how planning activity reacts to the phenomenon where it

is most observable. The selected cases are Treviso, Modena, Udine, Vicenza where, in 2011, the empty units in ZTL reached 41.8%, 38.8%, 37.9%, 37.5% of the total units, respectively, see Table 1.

The documents are available online in the official webpages of the municipalities. The research analyzed if and how the city planning documents react to the underutilisation phenomena, see Table 2:

- if the underutilization is reported;
- if sustainability is among the goals of the city;
- if the built heritage in the centre is considered an asset to exploit and reduce the consumption of land, establishing in this way a direct link between the phenomena and an efficient and sustainable use of resources;
- if innovative rules are established to both facilitate the regeneration process and conserve the heritage;
- if new developments and land consumption are planned.

Table 2. Table comparing the city plans.

	Treviso	Udine	Modena	Vicenza
Region with a City Planning Legislation	Veneto	Friuli Venezia Giulia	Emilia Romagna	Veneto
Number of Inhabitants 2011	81,000	98,000	179,000	111,500
Empty Units in ZTL in 2011 (% Total)	41.8	38.8	37.9	37.5
Empty Units in the Historic Center	2,127	1,344	3,238	2,097
Population Variation 1991–2001 in ZTL	–5.41	–8.30	0.98	–2.11
Type of Plan Governing the City Development	Strategic plan PAT and action plan PI	Structure plan PS and city plan PRGC	Structure plan PCS and action plan POC	Strategic plan PAT, action plan PI, master plan of the historic center PCS
Date of Enforcement of the Plan	PAT 2015, PI? (new adoption 2018, not approved yet)	2012	PCS 2013, POC 2014 (new adoption 2018, not approved yet)	PAT 2010, PI 2013, PCS 1979
The Plan Reports the Under-Utilization of Units in the City Center	Only partially	NO	Yes, since 2006	the plan reports a change in population, not underutilization
The Plan Defines Restrictive/non-restrictive rules for the Transformation of the Heritage	Restrictive (categories of action in compliance with Law 456/78)	Restrictive (categories of action in compliance with Law 456/78)	Restrictive (categories of action in compliance with Law 456/78)	Restrictive (categories of action in compliance with Law 456/78)
Main Goal for the Actions in the Historic Center	Revitalization	Natural shopping mall	Main reference for the development of the community	Open air museum
The Plan Introduces Some Innovation in the Actions for Heritage Conservation to Contrast the Phenomenon of Under-utilization	The 2018 update of the action plan does. Some actions are allowed in the general restrictive approach, such as flexible uses, multistorey parking, tactical transformations . . .	NO	The 2018 update of the action plan does. Some actions are allowed in the general restrictive approach such as improved accessibility, touristic promotion . . .	NO
The Plan Considers the Historic Center as a Relevant Resource to Accommodate the Need of Housing	It is declared, but the center is mostly considered for economic growth	NO	NO	Only partially
The Plan States the Need of Containing Land Consumption for Sustainability	YES	YES, zero growth is the goal	YES	YES
New Developments Planned Enlarging the Existing Urbanized Area	YES	YES	YES	YES
Foreseen Increase in Population in the Municipality Despite the Current Population Decrease or Stability	17%	17%	Information not available in the documents online	13%

The reading focused on some key terms: Underutilization, heritage, centre, conservation, sustainability, sustainable development.

The research analyzed the spatial planning documents because they are the manifesto of the public and the official position assumed by the local governments in recent years: The research produced an

exegesis of the texts and maps which compose the city plans as a critical assessment able to decipher urban planning stories and their coherence with the current reality.

The analysis shows the planning documents in force only recently started to acknowledge the problem and only a few policies were proposed to actively revitalize the centre. The research assumes it as evidence that the concept, tools and procedures of planning and regulatory practice – matured over the course of decades of economic and demographic growth – should be updated to be able to react to the structural changes in Italian society and economics and to the new – however, not really new – urban dynamics and mega-trends.

3.1. City of Treviso, Acknowledgement of the Phenomenon in the Bigger Picture but Late and Limited Action

Treviso, Veneto Region, has 81,000 inhabitants and 1600 inhabitants in the 24 ha of the ZTL in the heart of the city centre [25]. Treviso has a strategic plan, approved in 2015 (Piano di Assetto del Territorio – PAT) and an action plan, adopted in 2018 (Piano degli Interventi – PI) [28,29].

PAT registers some cases of underutilized or unutilized building stock, but does not acknowledge the phenomena of abandonment of the historic centre, which was already evident when the drafting of the plan started. The document which defines how much the city can grow in relation to what already exists classifies only the un-let units as the unutilized stock, assessing it to be 8.5% of the total availability, and declares it is non-recoverable and, therefore, not relevant to answer the present and future demand [30,31].

Despite the general goals stated – intensified requalification of the existing stock and historic and cultural identities as strategic assets for economic growth – and despite the population decrease by 2.16% in the municipality and by 11% in the city centre between 1991 and 2011, PAT foresees an increase in population of 14,500 units, almost 17% of the existing population, and urbanizes new areas to accommodate this increase.

In the strategic actions for sustainable urban regeneration (*ambiti dei programmi complessi*) the historic centre is not included, even though its requalification would require minor urbanization investments compared to the targeted abandoned large areas, twentieth-century complexes in peripheral areas that no longer respond to any use; these are very evident to the inhabitants and represent a problem for the local governments, while the centre clearly does not.

More attention to the city centre is given in the action plan – PI adopted in 2018, see Figure 2. It claims the need for actions for containing land consumption and revitalizing the city centre, allowing more flexible uses, multistory parking in dismissed structures, public-private use of parking. PI almost halves the amount of new residential developments and pursues the return of inhabitants to within the perimeter of the historic centre, and in considering the centre as an asset, PI also mentions the tool for temporary reuse introduced by the regional legislation for the containment of land consumption: To activate a process of regeneration of the abandoned or unused building stock with tactical interventions, waiting for a more substantial and definitive restructuring operation [32,33]. PI is a step forward because it clearly identifies the problems associated with the city centre. However, this action is late and limited considering the significance of the issue.

3.2. City of Udine, neither Acknowledgement nor Action

Udine, Friuli Venezia Giulia Region, has 98,000 inhabitants and 1700 inhabitants in the 38 ha restricted traffic zone [25]. The city planning documents approved in 2012 (Piano Strutturale – PS and Piano Regolatore Generale Comunale – PRGC) do not acknowledge the abandonment of the city centre and, therefore, do not give it a role in the actions for future sustainable development; generally, the plans give a representation of a city without severe problems [34].

Considering the slow demographic trends, PRGC reasonably defines the population in 2025 as 101,666 inhabitants and defines the normal un-let units in the city at 8.8%. Nevertheless, to answer the diverse housing needs, the plan adds 12,270 units to the existing ones, corresponding to a total

population of 117,050 inhabitants (+17%). To answer this future demand, the Piano Regolatore Generale Comunale does not specifically plan the requalification of the stock in the centre [35,36].

Figure 2. Excerpt from the Piano degli Interventi – PI of the city of Treviso, 2018; zoning and regulations of the historic centre.

PRGC mentions the goal of enhancing livability and re-qualifying the most valuable heritage to increase its attractiveness, but proposes some remarks that are unconnected to specific actions. The main idea, which shows some worries about the centre, is to consider the centre as a “natural shopping mall” in order to compete with the extremely successful shopping malls in the periphery, which have been massively draining customers and visitors since the 1990s. This idea proposes to reinforce the core without exploiting its identity, but adopting a model produced for different urban contexts. For this goal, PRGC proposes to enhance the public open spaces for pedestrians, mostly with projects of connections in the centre itself. This strategy seems to be out of focus, as the historic centre of Udine was designed and has always been a place for pedestrians and these connections are already there; in contradiction to this direction, the new local government in 2018 has approved to reintroduce car traffic in the ZTL.

The structural plan confirms the traditional interpretation of the territory around the Udine as a polycentric structure where the city is the most relevant core for its history and extraordinary urban quality; the plan also confirms Udine’s historic centre as the centre of this territory, when in reality, it is in a crisis of representation and vitality with a rate of 39% of underutilized housing units in 2011, a 70% reduction in local units of public institutions, and an 8.30% decrease in inhabitants.

3.3. City of Modena, Early Acknowledgement of the Phenomenon and Recent Attempt to Promote Actions

Modena, Emilia Romagna Region, has 179,000 inhabitants and 8900 inhabitants in the 72 ha restricted traffic zone [25]. The structural plan, approved in 2013 (Piano Strutturale Comunale – PSC), reacts to the underutilisation phenomena impacting the historic centre, a problem studied since 2006 [37,38].

PSC describes the constant transformation of the centre and focuses on two groups of actions, the first related to accessibility, rest areas, garages – declared as very relevant – and the second, to re-generation. For the first, the plan refers to further studies. For the second, it proposes to promote cultural and recreational activities, as well as commercial ones, and also refers to further studies for understanding the residents’ needs. The plan connects the requalification of some areas with reduced land consumption, referring to further specific policies [39].

The action plan approved in 2014 (Piano Operativo Comunale–POC and the related Regolamento Urbanistico Edilizio–RUE) fails to go one step further, that is to say, it neither specifies actions nor adds studies but adopts the usual and well-established practice for conservation: Almost every building in the city centre is subject to restrictive regulations (i.e., the Italian law defining the types of intervention: law 456/1978, art. 31), see Figure 3. In addition to these usual restrictions of transformation, increasing the dimensions of the buildings is always prohibited, as well as the change in use from shops, bars and laboratories into garages [40].

Figure 3. Excerpt from the Regolamento urbanistico edilizio – RUE of the city of Modena, 2013; zoning and regulations of the historic centre.

PSC gives a definition of the historic centre corresponding to the traditional idea of its values: The centre is a reference for the development of the local community, mostly for its public spaces and services which allow the inhabitants to be a community. According to this definition, the plan acts contradictorily: On one hand, it does not claim the recently diminished role, on the other, it includes the centre in the areas where public services are lacking, a new element to remark upon because the centre has traditionally been the place where services are concentrated.

Even if the plans in force do not propose an innovative approach to deal with the problems of the city centre, the revitalization of the historic centre with active policies has been discussed at a higher political level since the first months of 2018 and a new POC was adopted at the end of 2018: Facilities for the residents, improved accessibility and parking areas, economic support and touristic promotion are the solutions proposed.

3.4. City of Vicenza, Some Acknowledgement and Some Action Limited in Purpose

Vicenza, Veneto Region, has 111,500 inhabitants and 3019 inhabitants in the 50 ha restricted traffic zone [25]. The strategic city plan for Vicenza, approved in 2010 (Piano di Assetto del Territorio–PAT), declares a “crisis of identity” of the city centre for some of the reasons explained by the present research based on the interpretation of the Census Data: New, poor immigrants, weak public services, poor commercial supply and inadequate recreational areas [41,42]. To cope with this crisis, PAT suggests to improve cultural, recreational and shopping attractions and tourism and considers the city centre as an “open-air museum”. The ‘museumification’ of the historic space is coherent with the age of the plan

for the city centre in force (Piano particolareggiato per il Centro Storico – PCS), which dates back to 1979 (but was drafted in 1969, see Figure 4), even though it was partially updated in 1988 [43].

Figure 4. Excerpt from the Master plan of the city of Vicenza, 1969; zoning and regulations of the historic centre.

Similarly, PAT declares that the city centre must again become the place of high-quality residences, because the migrant and mobile population, that is increasingly occupying it, will cause its decay. PAT does not recognize in the new inhabitants a possible way to revitalize the centre, nor does it interpret the city centre as one of the “eco-neighbourhoods” which it defines their high-density and potential for regeneration: The main concern about the centre remains the conservation of its beauty and characteristics.

PAT promotes sustainability as a principle for a general urban re-structuring, and it stresses dwelling units must be obtained by re-using and re-qualifying the existing stock. However, the action plan approved in 2013 (Piano degli Interventi – PI) plans to accommodate only 600 of the future foreseen 14,269 new inhabitants in the city centre, while the present research found 2097 empty units potentially available [44].

Vicenza can be considered a paradigmatic example of the well-established approach to conservation in planning – resulting from an extensive technical, as well as conceptual theoretical reflection and definition of practices which goes back to the beginning of the XX century [7,8,45,46] – consciously applied to deal with new conditions without updates or reframed regulations.

3.5. Structural Difficulties and Conservational Approach

Even though the numbers of vacancies are high and the value of the property not utilized seems to be of absolute economic significance, the city plans presented here fail to propose innovative policies to reuse the centre. A further step, i.e., to consider these actions as a way to reduce land consumption and recycle housing stocks, is only mentioned.

The paper proposes that the examined plans express a structural difficulty in dealing with the historic centre within renewed cultural and economic coordinates. “Structural” means pertaining to the long-term cultural and organizational essence of the Italian regulation mechanism for protecting the heritage: In order to be in compliance with the law, regulations tend to deny transformation rather than to define an operational approach, allowing agreement and compensations.

Italian urbanism distinguishes between policies of regeneration based on cultural values – the building type, the permanence, the historical-architectural legacy – and actions based on scientific and technological values – sustainability, de-carbonisation, reduction of energy consumption, etc. This separation is highly inefficient, this is also because, in Italy, the conservational approach is often overwhelming due to the extension of the classification of heritage to essentially everything old [47,48] and the idea that the historic centre – as a whole – is a work of art and, as such, it cannot be changed [49]. The risk of stagnation is increased by the lack of dialogue in Italy between the culture of design and the culture of conservation [50,51].

4. Four Paradoxes of the Italian Historic City Centres

The results of the research show that some paradoxes exist in Italian historic centres. They are part of the most precious heritage of the country, locations of monuments and beauty, guarantee the cultural identity, icons of well-designed open spaces and well-being, and of a high-density and efficient use of land. Therefore, they should be successful but the interpretation of demographic movements and property dynamics over the past thirty years in small-to-medium-sized cities in Northern Italy reveal these positive and advantageous characteristics do not prevent the relocation of the population, businesses and institutions. The critical recognition of these paradoxes – presented in the following paragraphs – should be the starting point for the re-framing of the policies for urban heritage which do not seem able, as the previous paragraph shows, to give a dimension to the problems and react to transformation dynamics.

4.1. High-density and Compactness

The sustainability of high-density settlements has been a widely discussed topic together with the opportunity to drastically decrease land consumption for new settlements [52–55]. The historic centre has used land very efficiently because the settlement is compact and has a high-density: Generally, the centre is many times denser than the rest of the settlements in the municipality (in Udine, Brescia e Modena the inhabitants in the historic centre per square meter are roughly four times as many as in the rest of the city).

Compactness and high density produce also proximity to public services and can support public transportation, which is convenient and accessible because of the concentration of people and activities. It can be said the city centre has the required parameters to be sustainable because it is compact and of higher density, in a word, it has already the main characteristics of an “eco-neighborhood” [56]. But the issue is socio-cultural and related to changed desires for living condition: the heritage value and the human-scale value of the history centre are not enough to attract residents; failing to recognize it is misleading.

4.2. Community Life and Local Identity

The human-scale dimensions and the quality of the public spaces in the historic centre are generally praised and said to guarantee both individual well-being and community life in well-designed gathering places, as very influential scholars have been claiming for decades [57–59], reinforcing this myth in the Italian cities. These physical characters, where the symbols of the local community’s identity are preserved, seem to reinforce the social bonds and cultural identity. The so called “New Urbanism” carefully considers these physical conditions and claims these should be re-proposed for contemporary settlements [60]. The image of the centre as a pleasant place is so anchored that even some shopping malls adopt the forms and dimensions of the traditional open-air historic centre.

4.3. Recurrent Re-generation and Accumulation of Resources or Embedded Energy

The large majority of the built stock in the city centre was built to last, has resisted centuries and was recurrently transformed or adapted to new inhabitants, requests or functions. The high quality of the structures, as well as of some ancient urban tissue, has allowed regeneration and renovation; the Italian Aldo Rossi and Giancarlo De Carlo clearly highlighted these historical and architectural processes and opportunities, well before the idea of sustainable recycling [61–63].

In the old towns, the economy has been circular for the traditionally limited resources and for the great value of the buildings and their location, long-term resilient practices were constantly adopted over the centuries for preserving the assets. Open public spaces were constantly improved and maintained for the community gathering for market, justice, religious events.

Conditions are radically changed and nowadays, possibilities are not considered limited anymore, but the money and energy embedded in the historical structures must be recognized and valued, as well as the regeneration opportunity, to neglect this potentiality when the world is praising recycling and circularity would be a waste [64].

4.4. Vanished Appeal

If, over the centuries, the centre was the preferred and most prestigious location for inhabitants and institutions and the distinction between the centre and periphery was sharp, today the trend has changed. The paradoxes lay in the fact that universally recognized positive characteristics do not impact the choices of inhabitants and institutions today. Even though everyone recognizes the centre's great beauty, even if high-density settlements are praised as one of the best solutions for a sustainable urban environment, even though the surviving community spirit allowed by the centre's spatial peculiarities is considered an antidote against the metropolisation, the past appreciation has vanished and the historic centre is not appealing.

The paper suggests this lost social and economic attractiveness is due to the structural mutations in Italian society and economics, not only since the economic crisis in 2008 but progressively since the 1990s, expressed in urban terms by the phenomena of sprawl [65]. In times of climate change, of circular economy and search for a new ecological balance, where the urban world is a major actor, laws and regulations which govern the urban heritage should face the contradictions the paradoxes pose and be questioned. The research suggests it is urgent politicians and city officials give a different value to the historic city centre; this topic has long been neglected and it is high time the battle for preservation is followed by another battle for the recycling of a stock of primary cultural, economic and social value.

5. Conclusion: A Renewed Cultural and Economic Approach to Recycle the Wasted Urban Heritage for a Sustainable Development

The analyzed city plans clearly show that the challenge of connecting built urban heritage and sustainability is nowadays in Italy not to protect heritage as material facts—a goal already achieved thanks to a rich history of theories and actions—but to safeguard its socio-economic vitality. The failure is due not only to the mega-trends of globalization which re-structure the geography of urban hierarchy but also to the inadequacy of planning tools conceived for different socio-economic conditions.

The city plans show also that the regulation system finds it difficult to adapt to the unforeseeable and generally fast urban dynamics and to renewed cultural and economic conditions. The link between the built urban heritage and sustainability is often claimed in theory, but not taken to the operational level: The empty inner cores are not considered opportunities to reduce land consumption and recycle valuable assets.

In the Italian cultural and economic contemporary context -stagnation particularly affected the small-to-medium-sized cities since 2008- a new set of policies have to be framed together with new planning processes. A renewed cultural and economic approach must also be adopted. This task must

be accomplished in the general frame defined by the guidelines of the international institutions for conservation and heritage but with operational details suitable for the developed Countries [66,67].

The new goals of the city plans should be to:

- survey in depth the phenomenon of abandonment and acknowledge its impact; consider the built stock in the historic centre as an essential asset to balance expansion and re-functionalize the built heritage resources;
- re-define what changes of the heritage can be allowed without diminishing its value; in doing so, the plan must consider if the dense regulatory mechanism, matured over the course of decades of economic and demographic growth, is an obstacle for innovative practices and what elements in the policies prevent revitalization;
- find a balance between “original” residents and the significant presence of foreign people;
- contrast mono-functionality connected to the development of specific services, tourism in particular, in order to rely not only on one source of revenues and maintain residents and vitality.

The future phase of the research will consider cases where the decline of the city centre has been successfully dealt with in Italy and in Europe; this research will not only consider spatial planning documents but how these are part of integrated policies: In fact, the city plan alone cannot solve socio-economic issues. For this goal, the financial mechanisms and fiscal incentives for promoting the conservation of the historic centres and, at the same time, maintaining the inhabitants and the activities in the historic centre will be investigated [68,69].

Abstract: Since a few decades in many European mountain regions a process of economic restructuring is leading to the decline of traditional heavy and manufacturing industry. The issue of brownfield transformation is therefore becoming a crucial topic in the sustainable development of peripheral and rural areas too, although not yet officially recognized. The complex environmental, economic and social challenges posed by brownfield transformation in mountain areas, added to the structural limitations of marginal contexts as such, require the development of a context-specific, transferable strategy. In this perspective, the Alps, as the most developed mountain region in Europe, can play a key role as a laboratory for brownfields conversion. The first results of this research, which include a comparative analysis of the most representative industrial brownfield typologies found in mountain areas, suggest that an effective and transferable transformation strategy can be successfully developed only if a “landscape approach” based on structuralist planning principles is used. Through the development of an according strategy, the research wants to show that industrial brownfield sites can be positively and constructively interpreted, in the Alpine context and possibly in other mountain regions, as a valuable territorial infrastructure to be reactivated rather than simply a vacant land to be redeveloped.

Keywords: alpine industrial landscape, landscape transformation, brownfield recycling, mountain region

Brownfields in mountain regions – a special challenge

Due to the global structural change in industry since the late 1970s, the transformation of industrial brownfield sites represents one of the major challenges for the sustainable development of urban regions worldwide. Aiming to tackle the unprecedented land use change caused by the decline of traditional heavy industries, different planning strategies and tools have been developed and tested in the last decades (Ferber *et al.*, 2006). From the functional reconversion of vacant buildings and production spaces, also known as adaptive reuse, to the ecological-led conversion of polluted wastelands in post-industrial landscape parks, the issue of brownfield transformation has nowadays become an integral part of urban development plans and programs (Weilacher,

2008, Baum and Christiaanse, 2012, Braae, 2015). The global need to reduce the amount of landscape consumption after reaching “peak soil” (Fritz, 2010) fostered also the search for new strategies and methods.

The transformation of large scale industrial areas in densely populated urban contexts has been already thoroughly investigated (Dragotto and Gargiulo, 2003, Dettmar and Rohler, 2015). By contrast, peripheral rural regions are rarely examined as a setting for brownfield redevelopment. These landscapes are characterized by scarce urbanization, long-lasting structural development problems and in many cases by highly dynamic natural change processes, driven by high relief energy and recently reinforced by the effects of global climate change (Cherisch *et al.*, 2015). High mountain regions, for example, are very dynamic natural landscapes but so strongly tied to their stereotypical rural and recreational image that the presence of heavy industries, and thus of derelict industrial sites, are often overlooked (Nordregio, 2004). However, in many noticeable cases the cradle of a country's successful industrialization can be traced back to the early exploitation and industrial processing of natural resources in mountain areas. The Alps are an excellent model of this development, for example with regards to ironmaking and papermaking in Austria, the production of cement, textile, paper and iron in northern Italy or ironmaking, papermaking and electrochemistry in southeastern France. But the industrialisation of European mountain landscapes also took place in the Pyrenees in France (metalworking, electrochemistry) and Spain (metalworking, cement, textile); the Cantabrian Mountains in Spain (coal mining and ironmaking); the Carpathians in Slovakia (coal mining and ironmaking), Hungary (ironmaking and papermaking) and Romania (coal mining, ironmaking and electrochemistry); the Balkans in Bulgaria (coal mining, metal smelting and textile); the Caucasus Mountains in Armenia (metal smelting and electrochemistry) and Georgia (coal mining). In all of the aforementioned mountain ranges, the development of industry followed a mere functional logic, that is, to prioritize the cost-efficient use of local resources over the distribution to end-markets (Leonardi, 1998, Collantes, 2003). A first locational advantage was related to the on-site exploitation of natural resources and raw materials – such as water flows for mechanical purposes (textile and paper industry, metal forges), mineral deposits (ferrous and non ferrous metallurgy, cement and lime industry) and timber (paper industry and pre-coke ironmaking). A second one, crucial to heavy industries was the direct and costless use of independent generation of hydropower (energy-intensive heavy industries). A third locational advantage was the availability of cheap, and in some cases skilled labour force from the existing low-wage and low-profit agricultural sector. In this way, the industrialization of mountain areas assumed the character of a hetero-direct functional appropriation of existing environmental resources (Raffestin, 1989).

The mono-structure of mountain industry, attached to specific locational factors and highly dependent on external frame conditions, is the main reason behind the continuous deindustrialisation in the last decades (Perlik, 2019). As soon as traditional heavy and manufacturing mountain industries were hit by the growing independence from raw materials and energy sources, and the global reorganization of industry – with the relocation of basic production chains in highly accessible locations or in developing countries –, their inherent lack of resilience was dramatically revealed (Raffestin and Crivelli, 1988, Gebhardt, 1990). Especially in mountain areas, the consequences of the industrial decline in the last decades were severe and far-reaching for the social, ecologic and economic conditions. Not only did many people, often coming from small local communities, loose their jobs, left the region and added to a continuous depopulation of many inner mountain valleys (Bätzing *et al.*, 1996). The closed down factories also pose an enormous problem to mountain regions from an environmental point of view. Due to the specific characteristics of the mountain environment – namely the relevant topographic constraints, the prevalence of extensive semi-natural open spaces and the scattered urbanization – the decommissioning of industrial sites often generates extensive brownfields whose structural network reaches far beyond the core productive facilities and includes the complex system of supporting infrastructures and related functional spaces. It is most remarkable, for example, that most of the typical mountain industries were tightly connected to the complex local and regional water system. In many cases the artificial water systems generated during the industrialisation phase were not only connected as artificial bypasses to the natural water systems, but the industry also changed the natural water regime substantially. From an economic point of view, a major problem of brownfield recycling in such economically marginal

contexts is represented by the imbalance (real and perceived) between the amount of investments required for the entire transformation process and the uncertainty in terms of completion, achievements and returns. The high costs for the site preparation, including environmental remediation and built structures management (either demolition or preservation), are often burdening for small communities which lack of adequate financial and contractual capacities. At the same time, the lack of vision and long-term strategies, or even the conflicts between these strategies (where existing) and their feasibility, keep any potential private investor away from such operations. A further limitation is provided by the restricted range and/or scale of activities that can be really implemented in these sites, given the contextual conditions – low demand, few potential users, scarce accessibility, etc. It is not surprising, then, that the only successful reconversion projects in mountain areas are those related to the adaptive reuse of rather small sites (often less than 1 hectare) of local importance and projects related to the preservation of listed sites or buildings of historic interest (e.g. industrial heritage sites) (Lorenzetti and Valsangiacomo, 2016). Rather successful are also large-scale inner developments in major urban centres, where the pressure for land recycling is higher.

The Alps – a distinguished case study area

Located in the core of Europe, at the crossroad of strong economic regions and dynamic metropolises, the Alps were pushed through a modernization process far earlier than other mountain ranges (Bartaletti, 2011). This caused the emergence of the different forms and cycles of industrial development, leading the Alps to be today one of the few existing mountain regions worldwide characterized by a mature industrialization (Bätzing *et al.*, 2005). At least four industrial development phases since the continental spread of the First Industrial Revolution can be identified (Raffestin and Crivelli, 1988, Gebhardt, 1990). The first phase (1850-1880) was that of the industrial transition (or updated) of pre-existing activities, such as ironmaking, lime/cement production and textile manufacturing. The joint action of new technologies (coke, steam engine) and new transport modes (railway) caused an upgrade in productivity and a spatial concentration of the earlier industrial activities in valley floors and transit corridors. In the second phase (1880-1960), the discovery and spread of hydropower allowed the creation of new heavy industries in electrochemistry and electrometallurgy, which made the “industrial fortune” of many inner and remote valleys. The third phase (1960-1980) was characterized by the rapid and widespread development of light industry in low added value sectors (mechanics, electric appliances, apparels and food). This process, which affected several Alpine and pre-Alpine regions, mainly occurred through forms of decentralized industrialization, such as branch-plants and industrial districts. The last and current phase (1980-today) coincides with the functional and economic integration of the Alpine region with the surrounding metropolitan areas and global networks. In this context, advanced industries in knowledge-intensive sectors are gradually developing in major Alpine agglomerations only, thanks to the high accessibility and the concentration of research centres, business incubators and urban amenities (Perlik and Messerli, 2004).

The current phase, however, is also characterized by the progressive decline and disappearance of the historical labour and energy-intensive industry established in the earlier phases (Gebhardt, 1990). This is clearly reflected in the shift of the secondary sector employment from 50% to 36% between 1975 and 2000, and even further down to 18% by 2016, registered across the Alpine regions (sources: Alpine Convention, OECD, European Commission, FSO). Compared to the national averages of Alpine countries, these numbers show that in the Alps a slightly delayed but equally relevant deindustrialization process is occurring. At present, 289 industrial sites in traditional sectors (ferrous and nonferrous metallurgy, chemical industry, building material industry, textile industry and paper industry) have been identified across the entire Alpine arc (Modica, 2019). Of these, 142 are already closed or downsized (Figure 1). The worst performances are registered in the sectors of textile industry (26 closed sites on 35 in total) and nonferrous metallurgy (24 / 35), while the less affected sector is paper industry (12 / 47). Building material industry, ferrous metallurgy and chemical industry are in line with the Alpine average of about 50% of the sites closed or downsized.

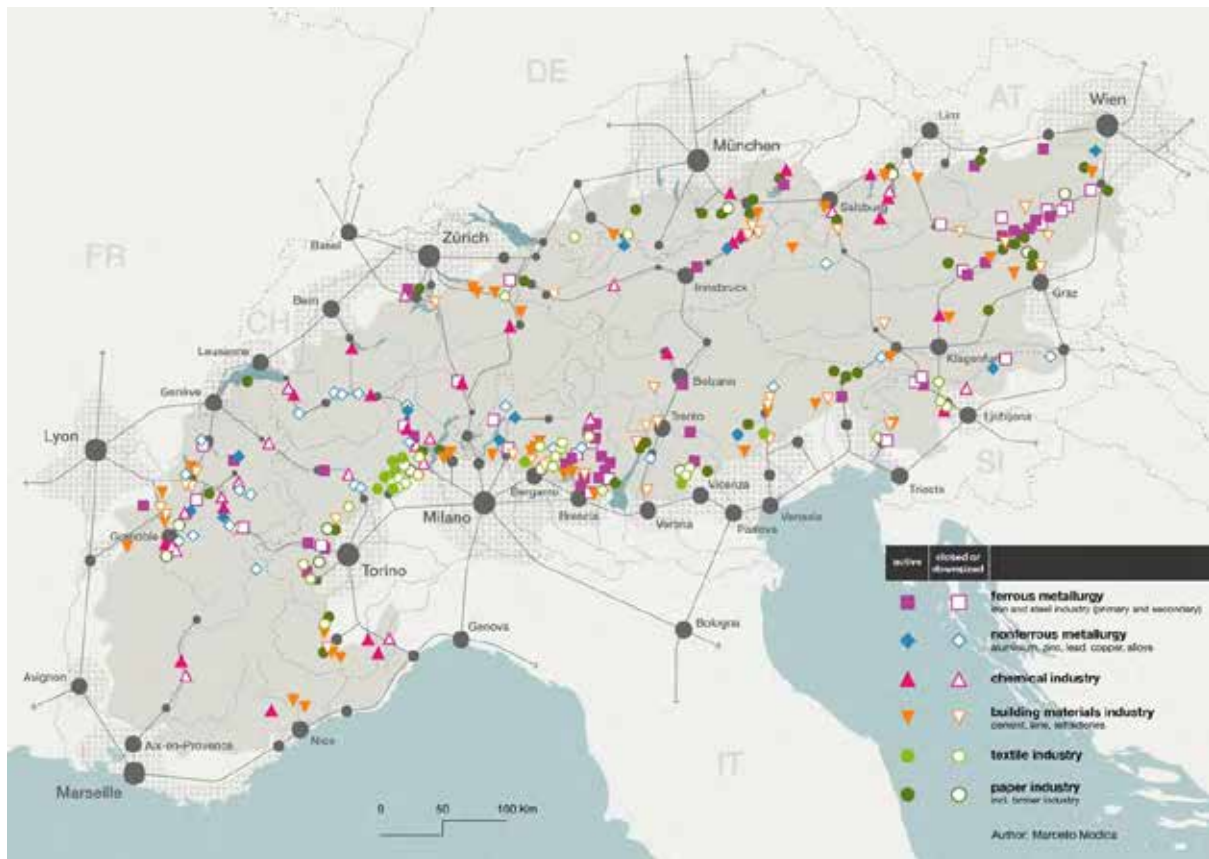

Figure 1 – Survey of large industrial sites in the Alps (elaborated by Marcello Modica)

Given this scenario, it is reasonable to expect that in many Alpine areas the already significant amount of disused or underused industrial sites will tend to increase in the near future. Although not yet officially recognized at the regional planning policy levels and by the scientific community, the management of brownfield sites is currently becoming a crucial issue in the sustainable development of the Alpine region. Three main challenges can be identified in this context:

- environmental regeneration: soil de-contamination from potentially hazardous waste (with expected positive effects beyond the site itself, e.g. in connection to rivers and groundwater), prevention of natural disasters (e.g. flood prevention and landslide protection), ecological compensation (e.g. soil de-sealing and improvement of disrupted ecological corridors);
- economic development: sustainable re-industrialization (e.g. making or reactivating space for small-scale business activities in green economy sectors linked to local nature-based production chains, innovation and research activities and business support centres) and multi-seasonal tourism (e.g. in connection to cultural heritage valorization, artistic events, etc.);
- socio-cultural development: prevention of rural depopulation and social desertification, improvement/sustain of local public services, protection of cultural identities

The Alps are a distinguished case study area not only because of its key position in the middle of Europe and its crucial importance to all six Alpine countries and their neighbours. This central European mountain region is, in fact, a unique socio-cultural complex integrated into a dynamic natural setting that currently transforms

dramatically under the influence of the global climate change (Grabherr *et al.*, 2010). Many of the brownfield sites are located at strategic key positions in the region with regard to the future development of sustainable living environments on a local and regional scale. By carefully combining the solutions to the above mentioned three major challenges at different administrative levels, the recycling of industrial brownfield sites will prove to be essential for the economic, ecological and social consolidation of the Alpine region. In this perspective, the Alps can be considered as a real laboratory (test-field) for brownfields conversion in mountain regions. The INTERREG Alpine Space project *trAILS – Alpine Industrial Landscapes Transformation*, initiated and coordinated by the Technical University of Munich, builds exactly on this vision.

Landscape typologies as result of industry-environment interactions

In order to identify and test potential strategies for the recycling of mountain brownfield sites, an in-depth analysis of the most representative site typologies has been developed as a preliminary cognitive step in the framework of the present research. The selection and analysis of site typologies has been managed in a two-step process. At first, three “groups” of industrial activities have been identified on the basis of the most relevant physical interactions between industry and the mountain environment, i.e. minerals, water and energy. Accordingly, four key production sectors have been selected: building material industry (mineral extraction), ferrous metallurgy (mineral extraction and large-scale hydropower), textile industry (water flow exploitation and small-scale hydropower) and nonferrous metallurgy (large-scale hydropower). A second step consisted in the identification of a specific productive site typology within the selected sector, connected to a basic productive process (function). The assumption is, that similar industrial activities generate similar spatial interactions, footprints and thus landscapes (form). As result, the following typologies of industrial landscape have been identified: cement plants (building material industry), EAF steelworks (ferrous metallurgy), spinning mills (textile industry) and aluminium smelters (nonferrous metallurgy). For each typology, six sites differing by location, status and size have been at first compared morphologically, based on a figure-ground analysis. As soon as the results were available, an on-site detailed analysis of one specific site per sector has been performed. This site analysis consisted in a prolonged site visit (one week) during which the site and the surroundings have been intensively and continuously explored and photographically documented, focussing especially on the spatial characteristics. The following paragraphs describe a brief descriptive synthesis of the four landscape typologies, supported by three representative images from the site visits.

Cement factories

The selected sites for the typological analysis are (Figure 2): Italcementi, Albino/IT – Wietersdorfer & Peggauer Zementwerke, Peggau/AT– Ciment Vicat, Montagnole/FR – Salanit Anhovo, Deskle/SLO – Zementwerk Eiberg, Schwoich/AT – Colacem - Gemonio/IT. The in-depth analysis has been conducted on: Zementwerk Eiberg - Schwoich/AT.

Figure 2 – Cement factories, typological study (elaborated by the author)

The driving force behind cement production landscapes is mineral extraction. The activities are usually organized around a cement production site (the cement plant) and one or more quarries for the extraction of raw materials (limestone, marlstone, clay). The topography is often complex and uneven (Figure 3): due to the location and nature of cement production, cement plants have a strong relationship with both natural topographic features (mountain slopes, depressions/canyons, etc.) and artificial ones (quarrying-related surface alteration). Although the average spatial footprint of cement plants is rather limited and compact (but highly fragmented in many buildings and standalone structures), the inclusion of quarries and quarry-to-factory connections makes the overall extension of cement production landscapes quite remarkable. The ratio between open spaces and built spaces largely favors the firsts, as the only buildings are concentrated in the cement plant site. More than the buildings themselves, which often stand out massive and prominent (Figure 4), are the open spaces the characterizing feature of cement production landscapes. Mineral “used” surfaces – such as paved areas on the premises of the plant, white roads connecting the plant to the quarries and the active quarrying sites – are often integrated with extensive natural/green “unused” spaces – abandoned quarrying sites and interstitial leftover spaces. The complexity of the cement industry landscape typology is at the same time a major challenge and opportunity with regards to transformation. It is a challenge in relation to its large footprint, whose management often requires a multi-scalar and multi-sectoral planning approach. But it is also an opportunity due to the already existing high level of integration of the (former) productive landscape into a wider environmental context. The site recycling potential lies here mostly in the extensive landscape alteration caused by mining activities (Figure 5), which can be turned, through selective renaturation and increased fruition, into new and valuable ecosystem services.

Figure 3 – Overview of the Eiberg cement plant from the Pölven foothills (copyright: Marcello Modica)

Figure 4 – The Eiberg cement plant along the rectified Weißache (copyright: Marcello Modica)

Figure 5 – The abandoned and partially renatured Neuschwent quarry (copyright: Marcello Modica)

EAF (Electric Arc Furnace) steelworks

The selected sites for the typological analysis are (Figure 6): Ugitech-Trimet, Ugine/FR – Monteforno Acciaierie e Laminatoi, Bodio/CH – Ascometal-Winoa, Le Cheylas/FR – Voestalpine Böhler, Kapfenberg/AT – Breitenfeld Edelstahl, St. Barbara im Mürztal/AT – SIJ Acroni, Jesenice/SLO. The in-depth analysis has been conducted on: Ascometal-Winoa, Le Cheylas/FR.

Figure 6 – EAF steelworks, typological study (elaborated by the author)

The driving force of mountain steelmaking landscapes shifted through the time from mineral extraction (iron ore) to the large-scale exploitation of hydropower. This technological upgrade, occurred at the thresholds of the 20th century, caused a major physical transformation of the productive sites, as well as their moving to favorable locations with plain topography and good railway accessibility. The activities are organized around a core production area (EAF site and rolling mills) and several additional “service” spaces for pre and post production activities. Due to the size of heavy production activities here carried on, the average spatial footprint of EAF steelworks is rather big, although the functional proximity between the production phases makes it also quite compact (Figure 7). Built spaces, which are often consisting of huge steel-framed halls with impressive footprints, give structure to the whole landscape, leaving to open spaces a marginal role as mere “extension” of buildings (Figure 8). However, while in the core area the form of open spaces is mainly related to roads and aprons, as physical separation between the buildings, on the edges of the site they increase by size and relevance. In fact, a system of functional wide open surfaces can be usually found in the proximity to the production site, such as large aprons for goods storage and by-product waste dumps (often with severe contamination problems). The stop of production activities and the closure of the site causes the progressive abandonment of these spaces, which are slowly camouflaged within the surroundings through spontaneous

renaturation. The recycling potential of EAF steelworks, however, does not belong either to open spaces and built spaces, but more on the existing infrastructural system represented by the in-out railway network (Figure 9). Although originally designed for production purposes, the complex railway system supporting EAF steelworks can be easily reused and adapted for other activities requiring the same infrastructure, such as logistic platforms or industrial parks.

Figure 7 – The Ascometal-Winoa site in the wide Gresivaudan valley, seen from the Brame-Farine. (copyright: Marcello Modica)

Figure 8 – The former rolling mill halls surrounded by leftover open spaces (copyright: Marcello Modica)

Figure 9 – One of the railway links between the site and the Grenoble-Chambéry regional railway (copyright: Marcello Modica)

Textile spinning mills

The selected sites for the typological analysis are (Figure 10): Cantoni ITC, Ponte Nossa/IT – Zegna Baruffa Lane Borgosesia, Borgosesia/IT – Seilerwarenfabrik, Füssen/DE – Linificio Canapificio Nazionale, Villa d’Almè/IT – BPT, Tržič/SLO – Spinnerei Hämmerle, Feldkirchen/AT. The in-depth analysis has been conducted on: Cantoni ITC, Ponte Nossa/IT.

Figure 10 – Textile spinning mills, typological study (elaborated by the author)

The driving force behind textile industry landscapes is water, originally exploited for mechanical energy production and later for electrical energy too (though in small scale). The activities of textile mills, and in particular of spinning mills, are organized in highly compact production sites, usually located in narrow valley floors in direct contact with rivers and minor water courses (Figure 11). In particular, spinning mills are often positioned strategically within meanders or at the entrance of gorges, as the particular topography of such locations (height difference) allows faster water flows. Within the core productive site, built structures are largely predominant over open spaces – often consisting in narrow lanes for small-scale product handlings and pedestrian mobility. The two most recurring building typologies, extensive shed halls and massive multistory buildings, are usually combined in complex and hyper-dense ensembles which literally stands out from the surroundings (Figure 12). However, if the system of artificial water-catchment infrastructures (canals, dams, basins, etc.) is also considered, as it should be, the spatial footprint of spinning mill changes completely. Due to the existing functional and physical linkages between the factory site and the river course, the first can be considered at all effects as an integral part of the river system, and so of the valley floor landscape. The recycling potential of textile mills lies indeed in their waterscapes, a symbiotic combination of built and natural heritage whose transformation might easily be connected to cultural landscape valorization (Figure 13).

Figure 11 – The Cantoni ITC cotton mill in the narrow Seriana valley. (copyright: Marcello Modica)

Figure 12 – Overview of the compact shed halls towards the centre of Ponte Noss. (copyright: Marcello Modica)

Figure 13 – A section of the artificial canal running through the factory site. (copyright: Marcello Modica)

Aluminium smelters

The selected sites for the typological analysis are (Figure 14): Trimet, St. Jean de Maurienne/FR – Novelis, Borgofranco d'Ivrea/IT – Montecatini-Alumetal, Mori/IT – Constellium, Steg-Hohtenn/CH – Pechiney, L'Argentière-la-Bessée/FR – Salzburger Aluminium, Lend/AT. The in-depth analysis has been conducted on: Constellium, Steg-Hohtenn/CH.

Figure 14 – Aluminium smelters, typological study (elaborated by the author)

Aluminium smelters are industrial facilities in which the electrolysis process is used to extract aluminium from its oxide (alumina). The driving force behind aluminium industry is therefore energy, and in the case of mountain regions, hydroelectric energy. For this purpose, aluminium smelters are often located in inner valleys where the higher elevation of reliefs ensure the necessary supply of water (Figure 15). In the first generation of smelters, the necessary hydropower was generated directly into the factory site, while in latest and larger facilities the same was transferred from massive power stations located in the vicinity. The spatial organization of the activities within the productive site is largely dependent from the size of the site itself. Older and smaller smelters have a rather compact footprint, which somehow recalls those of textile mills (with which they also partially share waterscapes), while bigger ones are more similar to EAF steelworks and heavy industrial sites in general. The relationship between open and built spaces is not univocal, being mostly influenced by the location, size and age of the facilities. On average, the open spaces are extensive paved surfaces functionally organized for internal transport and storage purposes, often integrating a basic railway network for in-out goods transfer. A particular feature of large smelters are the long-shaped electrolysis halls, massive buildings with a relative cheap, but highly flexible, architecture, which can be easily reconverted for new production purposes (Figure

16). Compared to the previous typologies, the high heterogeneity of sites makes difficult to identify, for aluminium smelters, a common recycling potential. In most of the cases, however, if the existing buildings are not suitable for an adaptive reuse (e.g. due to their conditions or size), the internal transportation grid (roads, railway) can be used as a "platform" for the implementation of new built structures (Figure 17). Redundant paved surfaces along the perimeter, for example, can be de-sealed, eventually decontaminated and renaturalized as ecological compensation zones.

Towards a common transformation strategy?

The survey revealed that many alpine countries and regions are dealing with the same kind of problems while trying hard to get brownfield transformation projects started and implemented efficiently. Especially the communities affected by deindustrialisation, often rather small and overstrained with planning tasks of high complexity, could solve their brownfield issues more efficiently if a useable and transferable transformation strategy existed. Although the transformation of each single site to a certain extent depends on the specific local context, the typological analysis allowed to identify a specific recycling potential across different sites, sharing the same productive background and landscape structure. If the regional context provides the frame conditions for the economic, environmental and social regeneration of brownfields, their typological specificity already includes the elements for their physical transformation. First test-design experiments (research by design) recently conducted on the selected representative sites, including different transformation intensity from radical to conservative scenario, are proving the validity of this approach.

A transferable recycling strategy for brownfields in mountain areas needs to help activating the full range of potential benefits connected to each single brownfield typology, while considering also the existing contextual limitations. This strategy should be based on at least three key principles:

- **gradualness:** to ensure a temporal “affordability” of the recycling process, a gradual and incremental development, organized around macro and micro phases with clear objectives, boundaries and actors, has to be considered;
- **flexibility:** to ensure an equilibrium between long-term goals and concrete, immediate achievements, a functional “adaptability” of transformation has to be also considered by assigning to specific categories of spaces the same macro-functions (production, leisure, environmental compensation, etc.);
- **inclusiveness:** the strong inter-dependance between the brownfield site and its context (local and regional) requires any potential recycling process to follow a spatial “coherence”, by considering the site and its context as a unique environmental, economic and social system.

To foster the operationalization of such principles, a “landscape approach” based on structuralist planning components is essential. By considering the existing landscape structure of mountain industrial sites as the result of the functional interactions between industry and the mountain environment, a sequence of different but complementary systems of built and open spaces can be easily identified. The integrated and gradual reactivation of these systems, driven by specific contextual economic, ecologic and socio-cultural needs, can help to set concrete and realistic planning milestones in the complex transformation process of mountain brownfields, thus easing its successful completion. Through the development of an according strategy, the research wants to show that industrial brownfield sites can be positively and constructively interpreted, in the Alpine context and possibly in other mountain regions, as a valuable territorial infrastructure to be reactivated rather than simply a vacant land to be redeveloped.

Track 1: Transforming built heritage and landscapes

(Draft)

Built heritage and landscape role in the Rome metropolitan plan

Lucia Nucci

¹*Departement of Architecture, University of Roma Tre, lucia.nucci@uniroma3.it*

Abstract: Built Heritage and landscape are long-term cultural and material memories constantly re-interpreted by the contemporaries. Both are considered as fundamental level for local and regional development in the Rome's Metropolitan Plan (Piano Territoriale Provinciale Generale PTPG). The Plan interpret nature, built heritage and landscape as key value that characterize the metropolitan identities. Settlement's transformations in the plan arise from the physical and historical form of the territory and encourage a double polycentrism (Rome and 120 municipalities). One of the general objective of the plan is to reorganize present settlement in made the most of existing patterns rules and peculiarities by using principles of the compact city. The paper would like to point out how built heritage and landscape development have to re-shapes the territories of our dispersal contemporary city.

Keywords: Rome's Metropolitan Plan, Built heritage, Piano Territoriale Provinciale Generale.

Introduction

This paper is part of a research project Between Rome and the Sea: cultural and environmental heritage, sustainable development and active citizenship. The territory between Rome and the sea is one of the most dynamic. The area is defined to the north by the Roman countryside of Maccarese and to the southeast by the Appia park and to the west by the Tyrrhenian Sea, crossed by the Tiber River. From the unification of Italy this part of the territory was made up of swamps and marshes. The main transformations took place at the end of the nineteenth century with the reclamation of the Agro, the location of an industrial (Ostiense) and the opening of the Agency for the Industrial Maritime Development of Rome (Ente autonomo per lo sviluppo marittimo ed industriale di Roma, SMIR). During the Fascist period, the opening of the railway from Rome to Ostia and the construction of the via del Mare gave a strong boost to the urbanisation. Since 1938, the area has been further equipped with the construction of the underground connecting Termini station to the Esposizione Universale Roma EUR neighbourhood, and the opening of the Ostiense railway station. The residential expansion between Rome and the sea will be supported in the post-war years, especially along Via Cristoforo Colombo. In the early sixties, the airport and the Rome-Fiumicino highway were added to the impressive infrastructure system. The strategic position and the infrastructures make this territory particularly attractive for offices. The area is characterized by the discontinuity of the urban settlement. From the environmental point of view, the area is characterized by the presence of two ... Archaeological complexes, such as Ostia Antica and Porto, await adequate enhancement as part of an effective integrated project.

The Research Project Background and Purpose

The interdisciplinary research analyzes the historical and contemporary reality highlighting cultural, environmental, urban values and problems. The aims is to offer a unified reading of the transformations that have taken place in the metropolitan territory in a long-term perspective.

Area of study: its characteristics and problems

Even at the beginning of the twentieth century the landscape of the Agro towards the sea was poorly urbanized: basically agricultural land, marshes affected by reclamation work. From the 1920s, the activity of the farmhands gave impetus to the rural building works and to the land reclamation. The system of canals created for the reclamation served as a basis for the appoderage of settlements. The first informal settlement was the Borgata Saline. In 1913 began the construction of the rural village of Acilia. The urban growth is characterized by discontinuity. Close to the 'historic' city, città storica, there are several neighbourhood such as Garbatella or EUR and important examples of modern architecture such as the INCIS district of Decima, or the social housing (PEEP) complex of Corviale and Laurentino³⁸, other suburbs, such as Spinaceto, Acilia, Dragoncello, Portuense and private neighbourhoods as Magliana, built in a flooding area, or Casal Palocco, built by the Società generale immobiliare, which offered the middle and upper classes a model inspired by the American suburbs, with villas and cottages and a wide range of services and green spaces. The fragmentation of the open territory is due to the urban sprawl that has profoundly modified the characteristics of the morphological-environmental system. The phenomenon is impressive: Isola Sacra, Ostia Antica, Casal Palocco, Infernetto, Dragoncello, Acilia, Centro Gianico, Casal Bernocchi, Vitinia, are a continuum of settlements that thicken along the main lines of connection with Rome, and then dispersed in the territory.

Land consumption is growing steadily: in more than a third of residential areas, the coefficient of land occupation is less than 10%. In the last three decades, public intervention has considerably reduced, while new private neighbourhoods was built beyond the borders of the Grande Raccordo Anulare (ring road). The landscape of the Agro still retains some of its distinctive features. Very important elements of the discontinuity of the metropolitan area are the great environmental systems consisting of the national parks of the Roman coast and Castel Porziano and the regional parks of the Tenuta dei Massimi, Valle dei Casali, Laurentina-Acqua Acetosa, Decima-Malafede. The research group is focused on the 'ordinary' urban heritage those types of residential settlements and landscapes in the Agro, interesting for their diachronic and multidisciplinary character.

Methods

For the purposes of historical reconstruction, the research will be aimed at the recovery and processing of documentary material of cartographic, pictorial, design and photographic type present in National and Local Historical Archives, as well as in libraries, private historical funds, metropolitan and local authorities (General Provincial Territorial Plan). The documentation and interpretation of the natural environment will be carried out from the descriptive point of view. This material will be elaborated in order to give back a diachronic image of the territorial transformations adopting GIS techniques that allow a precise analysis of the present realities. For the settlement system, the diachronic perimeter of the land occupation (PTPG) will be carried out at a detailed scale compared to the synthetic elaborations already present in the literature.

The research will increase the knowledge of different realities of the historical and contemporary city, considering that villages and centers of colonization as the elements that marking the phases of the transformation of the Roman Agro. On the level of historical research, thanks to the still unpublished documentation kept in various archives (such as the Central State Archives, the State Archives of Rome and the Capitoline Historical Archive) it will be possible to investigate economic-financial, demographic and environmental aspects related to the agricultural origins of the Roman suburbs. On the socio-economic level, the research will provide timely data on the selected systems allowing to test relationships and historical and current trends; on the territorial one, it will be possible to trace the theme of the models of settlement development in the different realities; on the environmental one, the selection of appropriate indicators will allow to evaluate peculiarities, differences and criticalities related to the phenomena of urbanization in progress. In terms of method, the research will provide comparative assessments through the development of a system of indicators

that will allow an understanding of the interactions between the different components and the creation of models capable of analyzing complex realities. A comparison with other European urban realities is also planned, which will be useful in the context of local policy perspectives. In the final phase, it is expected to undertake an active relationship with the municipalities that will aim to raise awareness of the citizen, with a hoped-for impact on the policies of management of the reality. The integration between historical-humanistic research and scientific-technological and design research aims to provide a model of territorial analysis that can also be compared at the international level. The importance of some compact city arguments for the project of the dispersal contemporary city.

Objectives and results that the project aims to achieve

The general aims of the project is to analyze - on the environmental, economic, social and with particular attention to historical, urban and settlement aspects – the territory between the city and the sea. The analysis will be aimed first at the acquisition of useful data for the description of the urban realities, including the types of the settlement construction, as identified in the Rome's metropolitan Plan (PTPG). At a later stage it will be possible to make comparative assessments by developing a system of indicators selected using appropriate statistical methods derived from the methods used in ecological modeling. The analysis and processing of data will be aimed not only at the description of the system, but also at the understanding of the interactions between the different components and the creation of models that can create a system able to analyze complex realities. The possibility of a comparison with comparable urban centers - in particular with other European cities - will be evaluated in parallel, thanks to a careful analysis of the literature able to show the dynamics underway. The integration of knowledge is expected to contribute to the knowledge of the territory, in an action that will aim to raise awareness of the citizen, with a hoped incidence in the management policies of urban reality. These operational aspects will be undertaken in the final phase by means of an active relationship with the Municipalities involved and thanks to the models developed both in the analysis of the Roman system and in other international experiences.

The research will allow to increase the knowledge of different realities of the historical and contemporary city, considering that villages and colonization centers have been the first stable settlement nucleus born in the context of reclamation, marking the phases of the transformation of the Roman Agro from territory malarial and uncultivated in urban suburbs. In terms of historical research, thanks to the unpublished documentation stored in various archives (such as the Central State Archives of the State Archives of Rome and the Capitoline Historical Archives) it will be possible to study economic, financial, demographic and environmental aspects related to agricultural origins of the Roman suburbs. On the socio-economic level, the research will provide precise data on the selected systems allowing to test historical and current reports and trends; on the territorial one it will be possible to trace with punctuality the theme of the models of settlement development in the different realities; on the environmental one, the selection of adequate indicators will allow to evaluate peculiarities, differences and critical issues related to the urbanization phenomena underway. In terms of the method, the research will provide comparative assessments through the development of a system of indicators that will allow an understanding of the interactions between the different components and the creation of models capable of analyzing complex realities. A comparison with other European urban realities is also envisaged, useful in the context of local policy perspectives.

The landscapes

The study area is characterized in the PTPG by the presence of two landscapes: Agricultural landscape of the Roman countryside beyond the Tiber; Agricultural landscape of the coastal reclamation Land (PTPG a, 2010).

Agricultural landscape of the Roman countryside beyond the Tiber. The landscape of this undulating plain located north-west of Rome is characterized by an extensive hydrographic network that has shaped the

orography of the area in a system of reliefs and valleys. In the larger valleys there are permanent waterways, often modified by the hydraulic reclamation (Consorzio di Bonifica del Tevere e dell'Agro Romano). Agricultural lands, in particular cereals and fodder are intended for the feeding of livestock farms (cattle and sheep). The morphology is characterized by a plot of small mountains but capable of dividing the territory into flat strips of elongated shape. The wooded areas are limited by agricultural activities, they appear very fragmented and follow the trend of the reliefs. These strips of wood are generally made up of evergreen or two broadleaf trees, mainly oaks. This type of forest represents an important natural reserve for the metropolitan area, hosting numerous plant and animal species.

Agricultural landscape of the coastal reclamation Land. These lands in the past was different. The marshy areas and the woodlands had a wide diffusion in the plain of Maccarese, inhabited and with a low density of rural settlements. These marshy and unhealthy areas was a national problem. The beginning of the reclamation has started in 1880. The agricultural reclamation has started this process of transformation of the landscape (9000 Ha) along the Arrone, definitively removed from the swamps only after the war. The present landscape of this part of the Agro Portuense is characterised by the presence of crops and agricultural settlements important for the metropolitan area. The agricultural production is variegated: it is mainly fruits, vegetables, cereals, fodder and zootechnics products (milk, meat,...). The agricultural landscape of these flat lands is characterized by the geometry of the cultivated plots, the canals and the streets in relief. The alluvial morphology guarantees ideal conditions for the cultivation of fruit and vegetable. Farmers from the northern Italy have encouraged the introduction of new techniques for these lands. Fields are surrounded by eucalyptus and poplar as wind-break and sometimes also rural buildings are characterized by the presence of these trees. This area preserves many archaeological testimonies. Urban settlements where they have fragmented the roman countryside in coastal areas. In the post-war period these marshy areas have been assigned to the farmers. This allocation affected a large area of agricultural land, divided into parcels, averaging 15 Ha. Over time further fragmentation of agricultural funds has been generated and this in some cases has led the abandonment of agriculture and the consequent transformation of the agricultural settlements in constructions.

The Central coast conurbation

The Central Coast conurbation is bounded to the north-west by agricultural land reclaimed (aree agricole di bonifica), to the north by the Tiber and the river plain behind the GRA, to the east of the Castel Porziano farm (Tenuta agricola) and south of the Castelfusano pine forest (pineta di Castelfusano). It is characterized by the three urban settlements of Fiumicino, Ostia and Acilia (located along Roma Fiumicino highway/Via Portuense/Via Ostiense/Via del Mare/Ferrovia Roma Lido/Via Cristoforo Colombo) and from the contiguity with the highway axis Rome-Fiumicino, director of connection with the airport and support of functions of metropolitan relevance (the airport, the interport centers, business and exhibition centres, large shopping centres, etc.) (PTPG b, 2010).

It is consistent the presence of additional metropolitan functions outside or mixed within the urban pattern (two marinas of Ostia and Fiumicino, the intensification area of Acilia Madonnetta, ...). Despite the significant environmental discontinuities (Tiber, River plain, green corridor and Castelfusano pine forest) that stand in between and separate the settlements, the tendency is to form a single suburbs, consisting of a composite patchwork settlement, largely determined by illegal building, where intensification area and manufacturing or commercial activities related to construction are confused in the suburbs and urban fringes.

The trend in local plans (piani regolatori generali PRG) is to establish along the Rome-Fiumicino highway and in the parallel Via Portuense activities of strategic interest, innovative functions related to the logistics, large shopping centers, large residential neighbourhoods. Decentralized along the Cristoforo Colombo, the old public neighbourhoods fit into private neighbourhoods recent or new. Along the coast, the trend in local plans is to develop tourism, boating and bathing, enhancing ports and existing facilities or offering new berths and new

opportunities for coastal accommodation without any coordination interventions in terms of environmental protection, planning, accessibility.

Overall, the relationship between Rome and the sea does not seem to be resolved. At the same time, in the absence of a polycentric organization, municipalities are offering single plots for residential and non residential development. All major problems still remain open: the three urban settlements, the "sustainable" tourism along the coast and in the protected areas, the organisation of the axis of specialised metropolitan functions and the organisation of quality beach tourism in terms of equipment (backward in relation to the coast) and infrastructure (specialised and equipped with interchange points for public transport by rail and road).

City of the Sea (Municipalities of Rome and Fiumicino)

The aim of the metropolitan plan is: the design of an inter-municipal settlement that aims to strengthen the character of the three different neighbourhoods (Ostia, Acilia, Fiumicino), contrasting the tendency of a single metropolitan suburbs from Rome to the sea. In order to achieve this objective, the PTPG redevelops in a differentiated and coordinated way the different parts of the "city of the sea" (residential, seaside tourism, nautical tourism, cultural tourism,...), strengthening the elements of functional integration (road and rail network subway, urban services, seaside tourism services,...), morphological and environmental (coastal environmental system, Roman coastal nature reserve, Castel Porziano and Decima-Malafede, the Tiber river system). At the same time, keeps the "city of the sea" separate from the urban construction of Rome using as discontinuity the natural reserves of Castel Porziano and Decima-Malafede and the Tiber Valley, which in addition to constituting a large environmental reserve, is the evidence of one of the historical landscapes in the Roman countryside. The metropolitan functions along the Rome-Fiumicino highway must be organised in a separated distinct from the "city of the sea" due to the presence of the airport. The plan considers it as a privileged axis of localization for large equipment, very qualified and reinforces this specialization, excluding not compatible use and proposing the organisation of a dedicated mobility.

The plan provides the following guidelines for the design of the intermunicipal settlement structure (see Table TP2).

For the environmental system: to protect and to enhance agricultural areas with residual natural values (green belts) evidence of the historical landscape, in order to use these components giving order of settlement constructions and continuity (see REP) of protected areas (Reserve of the Coast, Tiber River Park, Castel Porziano, Decima-Malafede).

For the morphological settlement system: articulate the intermunicipal city in three neighbourhoods, distinct from each other and from Rome. The metropolitan plan expects the regeneration of the various parts of the 'city of the sea' (consolidated parts: Acilia, Lido di Ostia, Isola Sacra, Fiumicino; recent neighbourhoods along Via Portuense Via Ostiense-Via del Mare, Cristoforo Colombo,...) with interventions on public space, promotion of commercial high streets,... In particular, for the environmental and settlement requalification of coastal settlements the plan identifies a unitary project of reorganization of the settlement for the equipment of the Ostia promenade and some connection between the sea and the railway station. For the Ostia Borghetto - idroscalo buildings that have arisen spontaneously must be gradually replaced by the shipbuilding industry close to the spaces for leisure and cultural activities. For the settlements of Isola Sacra, Ostia Levante, it is necessary the prohibition of caravan deposits, barracks by encouraging the inclusion of areas equipped with small urban services.

For the functional system: to organize strategic metropolitan activities and services in four specialised clusters coherent and linked to the airport, separated by environmental discontinuities (see art. 69 PSM2) and accessible to the metropolitan mobility circuit; to organise the tourism in different models: quality, efficient and value-compatible bathing functions environmental (seafront equipment, nature areas and routes, cycle paths, circuit of

slow mobility,...) which are distinct even if they are related to those of the and to those of culture (routes, areas, etc.) archaeological and historical sites.

For the mobility system: provide for the interchange at Ponte Galeria between the new railway service FR9 (Nettuno-Campoleone-Ladispoli-Cerveteri); organize the road system, specializing in the Rome Fiumicino highway with other dedicated infrastructure to support strategic services (airport, Cargo City, Fiera di Roma, Commerciti,...); organise the metropolitan road network (Via Ostiense, Via C.Colombo) together with the railway system (FM1, FM5-FM6) for the connection of the "city of the sea".

The Production of Heritage

Michela Pace¹, Alan Chandler²

Abstract: Urban regeneration is one of the operations through which global cities are tackling the increasing need of housing. Since 2008 redevelopment concentrated on selected urban districts, the reliance on private sector funding favouring 'luxury' developments and a systematic change in property patterns. The most interesting dynamic within this new field of urban exclusivity is the linkage of culture and history to the regeneration process. *Heritage* is a dominant new rhetoric employed in the marketing of these operations, the use of which engages and usurps political and administrative authorities able to facilitate urban development. The inclusion of the *Heritage* agenda concerns the restitution of urban legacies, becoming a selective concept which supports exclusive occupation, opening issues of accessibility and spatial democracy. The recurrence and extension of this phenomenon requires us to reflect on political and economic deviations that the promotion of urban legacy generates, both in terms of its spatial consequences but also in the cultural redefinition of who inherits the city. London and Shanghai are observed as case studies of what is now a global phenomenon, and reveal how the 'production of *Heritage*' becomes a regeneration driver supporting the market economy.

Keywords: heritage; regeneration; neoliberalism; visual rhetoric

Introduction

Heritage is an inheritance that both constrains and increasingly enables development. It is simultaneously a reason for the conservation of some parts of the city and for the demolition of some others, a symbolic asset to be returned to the collectivity and an economic value to be privatized, an image of local identity and an opportunity to tap into the global rhetoric of national representation.

It is argued that the expanding allusion to heritage has an active role in enhancing the economic value of the interventions through culture. The observation of communication strategies and promotional images allows us to understand how the simplification of meaning utilized in advertising development translates into the simplification of inhabitation and our relationship with historic environments and buildings. It is also argued that the 'imaginification' of architecture that passes through the rhetoric of heritage, has practical qualities and spatial consequences which affect the way we can inhabit the city. In particular, a shift towards a form of romantic consumption turns architecture into feelings, creating places that prioritises visual experience instead of practicality. Despite the declaration of a strong character, these spaces, and the images that define and represent them are tensionless, stripped of any form of social conflict or reflection and mediated by a socio-political process.

Two tier cities are taken as case studies to reflect the global diffusion of the trend: London and Shanghai. London has a central role in the network of financial interests linked to real estate, and it has, at present,

one of the fiercest and most aggressive housing markets in the world. Its intermediate (and uncertain) position between Europe and the rest of the world allows some leading trends to be particularly influential. The focus on heritage is linked to the priorities of neoliberal policies which exploit anything bearing a trace of uniqueness and identity in order to optimize value and transform spaces and buildings into a product. Shanghai is used to show how, despite a different background, real estate communication strategies align in these antipodal cities. Shanghai is the financial centre of China, as London is for Europe, and represents a preferential partner for the UK in terms of investments. Its forefront role in the process of urban renovation and its everlasting attitude of rebuilding itself as a global centre render this city an interesting outpost of 'red neoliberalism'. The regeneration of heritage, in this context, is very much part of the modernizing effort of the city, and many redevelopment schemes involve buildings with historic significance. The method used to study the rhetoric of regeneration in London and Shanghai, includes both an analytical approach based on images observation and on field research based on space analysis interviews. The first method revealed how communication strategies are used to select and promote spatial features through images. The second one unraveled the physical consequences of a highly symbolic and monetary approach with consequences on the accessibility and practicability of the city. In particular, the observed case studies suggested how heritage is promoted as an element defining both emotional responses and economic possibilities, and how the projects favoured episodes of exclusion and expulsion in the name of cultural restitution.

Heritage as a regeneration driver

The projects for the city have always been symptomatic of current political and social trends. The rhetoric that guided them has changed, involving for example aims of expansion, the research of a new spatial order and social tendencies (Secchi, 2005). It is argued that references to the past have always been part of the modernizing effort of city building, and that they have now become key regeneration drivers linked to financial operations (Figure 1). With nation states desperately active in promoting viable products for the global market, heritage has grown increasingly linked to branding. The market, eager to differentiate the product in order to sell exclusivity, commodified anything bearing a trace of identity. In this way heritage became a vehicle for economic appreciation. This trend can be observed at the global level: many cities all around the globe, while facing problems of population growth and land scarcity, are busy extracting as much value as possible from on-site resources (Sassen, 2017). Historic legacy is considered one of them, and is increasingly privatized as exclusive good, or bought as everlasting investment. Two effects accompany this tendency. Firstly, the conception of heritage enlarges from the one being referred only to old building to include entire neighbourhoods, modern edifices and cultural practices. Secondly, the restoration of these areas always entails a strong inclination to privatization, where mixed-used projects tends to be exclusive and to kick off gentrification processes. The value of heritage, in the end, becomes inevitability linked to the economic value that these operations involve; and to the extractive activity typical of neoliberal modes of space promotion and production.

Figure 1. Hoarding advertising heritage as a key aspect of the development, Shanghai 2016. Source: picture by the authors.

What needs to be clear is that heritage in itself is not a thing. Rather, «heritage is about the process by which people use the past – a ‘discursive construction’ with material consequences» (Harvey, 2008: 19, Smith, 2006). This means that heritage is a selective concept which does not necessarily involve history, as history would entail a more careful observation of the facts and their implications. Heritage can be easily isolated and rearranged to inform a bespoke narrative. At heart, it refers to «the ways in which very selected past materials and artifacts, natural landscapes, mythologies, memories and traditions become cultural, political and economic resources for the present» (Graham and Howard, 2008: 2). Present concerns, therefore, are the temporal dimension of heritage. Its construction is closely linked to the notion of ‘memory’ which, differently from history, seeks an uncritical relationship with the past (Nora, 1989). If portions of the past can be extracted from a wider narrative and attributed special value, it is easy to understand why certain materials have been selected rather than others. Economic convenience and social privilege are some of the reasons that guide the shaping of material and cultural significance, and its circulation.

Observing these mechanisms reveals how the process of selection has been made, and who is the final beneficiary of a certain interpretation of heritage. As stated by Hobsbawm and Ranger (1983), «we should look at those mechanisms that, deliberately or unconsciously, collaborate in their production. On the one side the marketing strategies that make them readable, the rules that guide planning, and the languages used to convey and distribute an idea of city. On the other side the mechanisms that make these strategies possible, and therefore the market, with its enabling power and its branding attitude». What is at stake is not only the concept of past and the power of history, but also our ability to imagine alternative futures.

London and Shanghai – two tear cities promoting heritage

Europe and China, in particular, are observed as preferential places where the rhetoric linked to heritage has evolved bounded to special political and economic meanings.

London is the preferential case study because of its fierce real estate market, and its role as an international node of financial flows attracting foreign investments. Here, historic buildings are being increasingly appropriated by wealthy groups, and used to mask financial operations with the pretext of urban restitution. This is supported by the making of bespoke narratives that build on the legitimizing presence of history. If we assume that heritage is ‘made’ and not inherited (Graham and Howard 2008),

and that memory «works by reinvesting places with new accretion of significance» (Kearns and Philo, 1993), we understand the pivotal importance in observing cultural narratives.

Aware that the centrality of the European continent is fading, (Indovina, 2015) we interrogate similar mechanisms in other parts of the world. For this reason, China, and Shanghai in particular, have been included in the study. The reasons involve the rising importance of Shanghai as a tier city, the growing attention that matters of heritage and national promotion are acquiring for the Chinese government, and the privileged relationship existing in financial and political terms between UK and China. Moreover, the scale and the speed of regeneration projects in Shanghai, together with a simplified system of rights, make China an interesting place to look at not only as a major overseas investor, but as active realm of practice. Especially after the recent statements of Xi Jinping at the Communist Party in November 2016, it is necessary to interrogate what China is uploading on the global stage of real estate strategies. This can be considered as one of the forefront markets where the process of nation building on the stage of the global economy is more competitive.

Clearly, we need to remember that London and Shanghai are representative of distinctive political and economic systems, which also evolved through intertwined but different paths. The rhetoric used in the two systems are therefore representative of local and national specificities and simultaneously of global tendencies, coming from the need to compete on the world stage of leading economies. The parallels between the two cities concern the mechanisms underlying communication strategies, but also the contents of city marketing. Above all, notions of heritage and memory recur as elements able to drive the success of the regeneration projects, and to assure a high symbolic and monetary value to real estate products.

Battersea power station – London

The project for Battersea Power station, part of the Opportunity Area (OA) of Vauxhall, Nine Elms and Battersea in London, concerns the rehabilitation of the famous grade II* listed power station erected in 1933 in Wandsworth and dismissed in the 1980s (Figure 2). It is advertised as having c. 4.000 new homes, 7 hectares of new public space, 3.174 parking spaces, 8.340 bicycle spaces, 2 medical centres, 2.000 capacity venue, c. 30.000 sqm of community, cultural and leisure space 450 m of direct river frontage 150 shops, boutiques and kiosk, 40 cafés and restaurants, exclusive hotels. Its position, on the west corner of the OA, offers a magnificent gate of access to the project, a square at the end of the Thames Path and a great occasion to glorify the historic building that, more than others, drives the symbolic evolution of the area. Well-known architectural firms were called to deliver portions of it: Ian Simpson Architects are responsible for the apartments, offices and shops called Circus West on the railway-side; Norman Foster and Frank Gehry are inputting the scheme with some mixed-use buildings, called Battersea Roof Gardens and Prospect Place; BIG is designing the Malaysian square at the end of Electric Boulevard; and Wilkinson Eyre is taking care of £1bn refurbishment of the power station, with the rooftop gardens being designed by landscaper Andy Sturgeon. The power station itself will be turned into a shopping center, with three floors of retail (as envisaged by developer David Roche 30 years before), a floor of leisure, a 2000 capacity arena and offices to be partially occupied by the Mac creative quarter. Cafés, bars and restaurant will be placed around the corners of the turbine hall and two additional glassed volumes with 245 apartments will be built on the roof between the chimneys and above the boiler house. Some of these apartments were sold off-plan for almost £4m, and one studio flat was sold in 2014 for £1.5m, which is how much David Roche paid the entire building and the land in 1984 (Watts, 2016: 217).

Figure 2. Battersea power station under reconstruction seen from an adjacent neighborhood, London 2016. Source: picture by the authors.

When it was featured in 2013's Open House London, the architectural festival opening close doors to public viewings, more than 40.000 people queued for hours to have the chance to have a look inside the power station (Watts, 2016). Commonly defined as one of the symbols of English industrial genius, and excellent example of industrial *art deco*, the design of Battersea is inevitably linked to Sir Gill Albert Scott, the architect that authored the red kiosk, or phone box, in turn inspired to traditional architecture. Since the 1980s a number of projects confronted with this legacy, proving how the regeneration of the built environment needs to be observed alongside the regeneration of political, economic and social ambitions which support it. Every time, a renewed context created the opportunities, and then dismantled them. Its functions evolved, different subjects took part in the discussion, national and international interests were involved. The cultural industry, among the others, started to appropriate the building. Pink Floyd, for the launch of the album *Animal* in 1977, hang the famous pig Algie between the chimneys. Beyond the political meanings, this was the first cultural operations –later followed by many others - that contributed to increase its symbolic and representative value of the power station in the eyes of citizens and investors alike. It's not by chance that the Malaysian company currently leading the regeneration project cared about conserving the appearance of the symbolic chimneys, recognizing their 'value' in so much that some renders depict them from the same perspective that was once of the Pink Floyd album cover. However, the anxious aspect given by the contrasting tones and dark shadows (in line with the contents of the album), are replaced by a more pacified version of the landscape, suggesting harmonious and communal feelings.

Other characteristics from the past are recalled with insistence within the project's advertisement. They are presented as proof of originality, showing a mixture of enduring qualities linked to heritage references, and pioneering entrepreneurial experiences representing a «new chapter» for the city. By highlighting the continuity with the past, the promise of reward is almost granted, as suggested by the mentioning of successful moments in history that brought London to prosper. At the same time, the fascination for built and cultural heritage permeates the descriptions. Interiors showing exposed bricks, steel furniture and industrial style windows are countless. By evoking 'Englishness' through the use of symbolic references, the innovative spirit that animated the construction in the 1930s is recalled, and a bridge is immediately built towards the innovative intents that moves the project today. «This was no ordinary Power Station, no ordinary design (...) Sir Giles Gilbert Scott's design of Battersea Power Station turned this immense structure into a thing of beauty» (LIVE brochure). The preciousity of these interiors where «glamour meets industry» is explained by the fact that «an iconic British building deserves the best of British design – the interiors will have an industrial yet luxurious feel» (LIVE brochure). The power station's industrial past become, in this sense, a design bonus. The iconic status

of the power station seems to emanate on the rest of the buildings, transferring its deposited value onto branded buildings in desperate search of looking contemporary. «Battersea Power Station is London's quintessential industrial landmark, built to last on a heroic scale. Its rawness and atmosphere are its authenticity and must drive aesthetic decisions throughout the design process, inside and out, from the word go. Lose this and you lose The Power Station» states point 7 ("Industrial Magic") of the Battersea Manifesto (The Placebook).

Besides than at a formal level, the continuity with the past is evoked also at a functional level: Battersea power station, once a symbol of technological innovation, will host the new Apple headquarter, a campus able to host 1.400 employees. The ameliorative quality of the project is evident: the polluting image of the power station, that fueled the dissents at the beginning of the 20th century, is being replaced by the 'white apple', symbol of the cleaner and most efficient design on the market in the 21st century. Moreover, Apple is in a way, the quintessential incarnation of the contemporary creative industry. Popular, 'different', polished and global. Started from the garage of a creative, it now occupies one of the biggest symbol of power in one of the richest capitals on earth. In the Battersea Manifesto, these new 'respectable dwellers' are presented as «the most valuable firm in the world by market capitalization» who, according to adverts, «will help create a thriving new community on your doorstep» (Powerhouse Magazine 6). This given proof of success accompanies the call for young creatives and independent shops. Images of workers from the 1940's, working inside the turbines of the power station become inspirational models of professionalism and invention. New «local heroes» are now the ones managing the coffee shops, the flower shop, or working as cooks on site. The image of the employee has been polished and substituted by the self-manager in search of creative opportunities. Indeed, the marketing of open possibilities ask for more attentive analysis: the range of opportunities are being addressed and selected to inform a specific image of city, as so have been the people who can access them.

Suhe Creek – Shanghai

A similar operation can be noticed in the Suhe Creek redevelopment – Shanghai, where the new plan aims to recover meaningful parts of the city. The Suhe Creek, a large urban complex set east of Henan Road and North Tiantong Road, along the banks of the Suzhou River, is fated to become one of the most discussed projects in Shanghai in the years to come. Led by state-owned Chinese developer Oversea Chinese Town Enterprises (OCT) and spread along the Suzhou Creek, the project rises on the site once occupied by old *lilong* houses, which have been promptly removed in recent years to make space to the regeneration.

The redevelopment includes 243 apartments on 27 floors, a luxury resort and a 48-storey tower branded by Bulgari, surrounded by lush, Italian-style gardens and overlooking the Bund. Adjacent to the hotel, sits the historic Chamber of Commerce Shanghai Building, a Neoclassical Renaissance building built in 1916 and restored in its former glories by the Italian architectural firm Antonio Citterio Patricia Viel. The same firm signed the luxurious Bulgari complex, while the early 20th century Ewo Packing Factory warehouse was restored by the Italian Kokaistudio – one of the pioneering architectural practices on heritage matters in Shanghai, and author of the lavish Bund18 refurbishment (2004). The urban project is overseen by world-class architectural design team Foster+Partners. The centrality of the creek which gives name to the regeneration project, has both symbolic and practical implications. The site, once home to the first settlements of the city, is now made available to new inhabitants who, it is implied, are moved by the same pioneering ambition of the old ones, this time carrying Bulgari watches instead of fisherman nets. Indeed, Bulgari is betting on brick as a luxury item: «“I like to think at the Bulgari Hotels collection as a necklace and today we added a sixth gem to it, in particular a precious ruby that is the stone that most represents the vibe of Shanghai [...] » stated Jean-Christophe Babin, CEO of Bulgari (CPPluxury, 2018).

The presence of heritage occupies a good part of the Suhe Creek marketing strategy. In particular, traditional concepts derived from Confucianism are exploited to render the project acceptable, and demonstrate how the manipulation of heritage not only involves material features but also cultural ones.

One of the most referenced concepts in the construction of livable spaces in China is “harmony”. The revival of harmony in recent political discourse can be traced to the speech made at the fourth plenary session of the Sixteenth Central Committee of the Communist Party of China in September 2004 by former President Hu Jintao. The subject of the speech was “building a harmonious socialist society”. Confucianism defined harmony as a framework for organising life and maintaining balance at different levels (Wang *et al.*, 2015). At the same time, it has become aesthetic and political doctrine, and this ancient concept can be observed in images used to represent new urban redevelopments. Here, harmony is found in tensionless representations where people meet naturally and conflicts are erased. This is realized, first of all, by excluding elements that don’t match the standard of the advertisement. The promotional video of Suhe Creek by Bulgari is a vivid luxury dream, where the empty hotel is crossed by a combination of rendering and filming cameras highlighting the preciousness of the environment. When diversity is recalled, this is done through the use of history, in this way distancing diversity as something belonging to the past. However, in Confucianism, it is “difference” not blandness that is the «precondition and cornerstone of harmony» (Wang *et al.*, 2015). Harmony presupposes the acknowledgment of difference as a creative tension generated through the interaction of different elements. The energy which sustains harmony is relational; it welcomes strain, conflict, and negotiation (Li, 2008). The images used to promote new developments translate these commitments into detached, homogeneous landscapes where conflict is absent. Harmony is twisted and flattened onto advertisement hoardings to recall an idea of order and beauty able to redress an increasingly unbalanced and unfair landscape (Yu, 2008). The centrality of heritage is clear, as it underpins the visual and ideological rhetoric of the redevelopment project becoming the joint between popular restitution and exclusive appropriation. The Suhe Creek project offers a good example of this. As you enter the marketing suite, a four-meter-long map from the beginning of the century supports your understanding of historical changes in the local area’ urban fabric. There is a short video titled “An historical celebration of Suzhou River”, explaining its role as a water route fundamental to the development of the local built and social environment. The video celebrates the renovation of the area as an act of final restitution. After the first video is a second one. This time for Bulgari. The video claims history as a continuous source of inspiration: a classical statue breaks into pieces and is covered in gold, while a Colosseum transforms into a ring. “Classic is Revolutionary” concludes the movie, not only providing the perfect synthesis of oppositions as a slogan, but also re-establishing a popular term (revolution) as part of a luxury creative genesis. The advertisement includes oppositional elements to the system rather than removing them, and makes the final message even more effective. It links simultaneously to classic style and revolutionary changes, to the past and the future of the city, to shared accessibility and privileged ownership, to preservation and demolition, all justified by the overreaching metaphor of heritage, charged in aesthetic resonance. Heritage is once again at the centre of a revolution, a driver of placemaking able to produce urban and social regeneration alike. On a much more immediate level, the concepts of past, inspiration, and nostalgia through which the Italian brand is made recognisable are successfully used to market the regeneration project and to inform the Chinese notion of harmony. Heritage becomes the language through which “harmony” is established – cleaning, ordering, reinventing a part of the city. This is proved by the advantaged position offered to the new inhabitants who will be able to enjoy «stunning views of the iconic Bund, Pudong financial district and the dramatic curvature of Huangpu River and Suhe Creek» (bdrconsulting, 2018). If in the past the poor fishermen had to immerse their bodies into the water, now the rich new inhabitants elevate up in the sky, where everything can be looked at, and a dinner is a matter of ordering rather than hunting. Harmony ends to be immersive and embraces the environment from a privileged point of view.

In the end, marketing materials show a new notion of ‘harmony’ – visual, instantaneous, natural, tensionless as opposed to experiential, conflictual, reflective and mediated by the economic and social process (Li, 2008; Wang *et al.*, 2015). However, the relationship between what is included in the representations and what is tolerated in the reality, often hide an implicit reference to a given social homogeneity. As Marin (1983) states, the harmonisation of opposites allows to reposition the subjects within a new framework: the authenticity of the pre-existing fabric is advertised together with a pioneering sense of romance and fiction (Klingmann, 2007) in order to create new identities and new urban communities.

The territorial function of heritage

In both cases it can be observed that the references to notions of heritage culture have a ‘territorial’ function: they become the channel through which to communicate, implicitly and explicitly, narrative of inclusion or exclusion. Surely within societies, «various groups insert symbols into the cultural landscape which resonate with their sense of heritage and identity, and which simultaneously incite remembering and mark territory» (McDowell, 2008: 48). In the globalized era, heritage continues to be a tool of selection and claim, but its meaning is more and more related to the financial appropriation of places. The processes of exclusion, expulsion and gentrification that often accompany the processes of regeneration demonstrate how heritage is being appropriated both materially and ideologically by wealthy groups. However, the ambiguity of its rehabilitation, the creation of open private spaces around it, and its familiar aspect, helps securing «the acceptance and even the affection of peoples who might otherwise rebel to it» (Philo and Kearns, 1993: 22-23). The case of Battersea is representative. While the building is ‘given back’ to the city with apartments sold at 19.000€/sqm, the icon of the same building has been included inside the British passport transforming one of the most exclusive operations of the last decades in a democratic symbol of national identity.

The simultaneous creation of a regulatory apparatus to support the regeneration operations feeds the selection. Among the examples, it seems interesting to dwell on the debate concerning the affordable housing in the UK, which imposes strong restrictions on accessibility to the home when London needs around 50,000 new homes per year to meet the housing needs of the population. In 2014, under Boris Johnson, the former Mayor of London, ‘council’ or social housing has been replaced by a new and more ambiguous product: the ‘affordable’ houses. A property defined ‘affordable’ can be sold up to 80% of the market value, unlike the previous council houses that allowed a rent equal to (approximately) 50% of the market value, a threshold that allowed many families to pay rent without being dependent on the so-called housing benefits. To answer the shortage of houses, the current Mayor Sadiq Khan had proposed that 50% of new homes built in London fall within these criteria. However, little after the 2016 elections, the limit was lowered to 35%. The Battersea Power Station masterplan that was approved in 2010, it provided 518 affordable units in three different locations. In 2015, some of these were pushed to their limits of the regeneration area with the excuse that this would speed up the delivery of the project and therefore the sale of the other units. In fact, the least expensive houses were removed. In 2017 Wandsworth Council allowed the entrepreneurs to reduce the number of affordable housing to 386 units (Byers, 2018) giving proof of how the projects of expulsion and gentrification that inevitably seem to cause an aggressive market, need a regulatory apparatus capable of actively supporting it. It is curious to notice how the present scheme recalls another one that was put forward in 1983. The plan proposed a mix of luxury flats, retail, a hotel and a marina. At that time, in the hyper capitalistic 1984, the luxury flats that now dominate regeneration were considered socially unacceptable, and the scheme was rejected as being “substantially outside the brief” because it was giving nothing back to the community.

Similarly, the restitution that granted by the Suhe Creek development is in fact exclusive. It is clear that after the erasure of the old *shikumen* houses, the place will not be returned to its original inhabitants. At the same time, a “harmonious” understanding of the relationships among subjects is applied: the ones competing over land consumption; the ones who structure and the ones who finance these redevelopments, and the ones who simply inhabit them. Obviously, this is not more than a fiction, where the shaping of livable spaces is dragged along by an economic system which selects object and styles as inherited capital from the past, but also selects people as one of the materials to be renewed (Rogers and Darcy, 2014). «One has to go deep into the course of history, understanding the past, this knowledge as a foundation for the future», says a quotation signed Nicola Bvlgari on the billboards. It shows a western woman wearing diamond earrings while posing inside an elegant interior. Other renders, flashy and glittering show the site from the top. The combination of images, swinging between black and white sophistication (Figure 3) and ostentatious shininess represents a diversified communication strategy able to talk to different publics. On the other side of the road, in front of the attractive woman, lays the site of popular *lilong* houses, now demolished to make space to Bvlgari.

Figure 3. Hoardings around the construction site of Suhe Creek, Shanghai 2017. It shows a western woman making up in a living room. Source: picture by the authors.

Conclusions

It is noted that the increasingly frequent allusion to heritage plays an active role in the promotion of value economic of urban regeneration operations. In the era of globalization, the growing need for preserving and promoting "identity", "culture" or "originality" is perhaps the last trick to add value to the landscape of the flattened real estate of global regeneration. The production of narratives related to heritage material and immaterial, it supports the recovery of local and national territoriality, and the value of the same territory is attributed. However, there are risks. Memory as representation risks collapsing the tension between past and present in an eternal present, and to use history as proof of certification and value (Huyssen, 2003). The heritage is restored and protected, assigned to those who can take care of it, and rebranded as an eternal symbol of culture. In this sense, the regeneration projects that call themselves "timeless", "Definitive" and "everlasting", do not contradict the concept of history so much, but testify to the intentions of capital. Thanks to the sense of legitimacy that underlies it, heritage helps protect long-term investments, and for this reason its value becomes more than symbolic: the conservation and promotion practice that concerns it ends to be a practice of safeguarding and promoting its economic value. Accept that the heritage is a highly political process means recognizing its flexible nature in relation to power and in relation to specific material and temporal contexts.

The identification of visual narratives linked to heritage rhetoric as a field of observation, and to economic discipline as a necessary context of confrontation, might contribute to fostering a cross-disciplinary attitude in the field of contemporary urbanism, and to promote specific directions of research. This can establish a set of scientific practices related to the analysis of visual narratives for contemporary urban development. This should consider the plurality of languages and representation as a resource beyond the ones put in place by leading powers. Deconstructing the codes and recognizing the mechanisms that support urban marketing can lead to elaborate strategies of resistance and appropriation. This not only concerns the language as a fundamental tool of democracy, but also its effects on place as the result of specific narratives. Working on alternative images might contribute to build different scenarios of social re-appropriation of both places and the historical narratives building them.

Developing transformation strategies for Alpine industrial landscapes shown by the Styrian Iron Route in Austria

Julia Pechhacker¹, Julia Forster²

julia.forster@tuwien.ac.at*

Abstract: The Alpine Space is one of the most important industrial regions in Europe. The transformation from manufacturing to service industry in the last decades and the decrease of traditional heavy and manufacturing industry are leaving impressive former productive landscapes of relevant size and complexity, so-called Alpine industrial landscapes behind. The potential value of these landscapes is linked closely to ecological, economical and social challenges in the development of these regions. No significant strategies or programmes for a transformation of industrial brownfields exist currently. The INTERREG project “trAILS ” deals with the topic of industrial brownfields and aims to generate knowledge about Alpine industrial landscapes. It shows how future development paths for these sites can be developed and visualised and thus serve as a basis for discussion, decision-making and planning for the definition of concrete planning recommendations for municipalities. The overall objective of the project is to discuss and develop ways of raising awareness of the strategic development of brownfield sites, a topic that will continue to gain in importance in future. The following contribution focuses on the first project phase, in which a process for developing a transformation strategy was elaborated and tested in one of four pilot regions.

Keywords: industrial brownfields, alpine industry, transformation strategies, sustainable transition

1. Introduction

1.1. Motivation

When thinking of the Alps, most people think of the beautiful mountainous landscape, alpine agriculture, tourism or winter sports. The term “industry” is probably not associated with the Alps by most people at first. Nevertheless, the Alpine region is one of the most important industrial locations in Europe.

Industry in the Alpine region developed mainly in the 19th and 20th centuries, but its importance is still greatly underestimated. Industry in the Alps evolved for a number of reasons, amongst others due to the occurrence of raw materials such as ore or minerals, the presence of a sufficient number of workers or due to the usage of hydropower for production with high-energy consumption. Depending on the local conditions and potentials, different types of industry, such as aluminium, chemical, magnesite, steel or textile industry, originated. (cf. Bätzing 2003: 136ff.)

Another important impact on the development of the industrial sector in the Alps was the development and provision of infrastructure, especially of rail-borne infrastructure. Therefore, from a European point

of view, the Alpine region represents an important trade link from north to south and vice versa. Many European transport corridors lead through the Alps. Valleys with good access to the transport network are then and now important transit routes for the carriage of industrial goods.

As in many regions of Europe, the decline of the traditional heavy and manufacturing industry can also be observed in the Alpine region. The massive mining of raw materials in recent decades has exhausted or even extinguished many of these sources. In addition, the increasing degree of automation in mining and production processes means that fewer and fewer workers are needed in industry. With the retreat of industry, a decline in the population can therefore often be observed.

This process is leaving impressive former productive landscapes of relevant size and complexity behind, so-called Alpine Industrial Landscapes. The potential value of these landscapes in terms of sustainable transformation is strongly linked to Alpine-wide ecological, economical and social key challenges, such as the regeneration and improvement of blue and green infrastructures, the reactivation and upgrade of regional economies and the promotion of local identity and cultural heritage. (cf. trAILS 2018: online)

To use the potentials and to face the challenges that arise within former industrial landscapes, an alpine-wide overview of the location and situation of these sites is needed. Currently no reliable quantification and qualification of industrial brownfield areas exists. Furthermore, no significant transformation attempts or conversion strategies have been developed yet and the awareness about potentials and challenges in connection with industrial brownfields has not been mentioned in previous Alpine development programs and projects. (cf. trAILS 2018: online)

An INTERREG Alpine Space project called “trAILS – Alpine Industrial Landscapes Transformation” deals with this lack of information about industrial brownfields in Europe, aims to generate knowledge about Alpine industrial landscapes and depicts how to transform such sites and how to raise awareness of this increasingly important issue. The motivation is to create overviews, not only across the Alps or on a national level, but also on a regional and local level. At the local level (in the pilot communities), the development of future pathways will enable concrete support in the transformation of brownfield sites and the derivation of concrete planning recommendations for local planning actors.

1.2. State of the Art

As mentioned in the introduction, there is currently neither a general overview about industrial brownfields in the Alpine region nor is the topic sufficiently anchored in regional, national or European policies, legislations or funding programs. Therefore, there are few or no strategies for dealing with industrial brownfield sites at present. One task of the project "trAILS - Alpine Industrial Landscapes Transformation" (see chapter 1.3) is to develop a strategic and transferable process that enables the sustainable transformation of brownfield sites.

It is therefore necessary to place different methods or sets of methods in a particular order or context which, in a first step, allows to locate industrial brownfields on different scale levels and to add selected quantitative and qualitative information to these sites. The methods and information must be chosen in such a way that in a next step, the potentials of the industrial region and the brownfields can be shown, as well as the framework conditions for a transformation of the brownfields.

One method is the visualization of data using GIS and web-based mapping. Different javascript based libraries like Leaflet, Open Layers (two-dimensional) or Cesium (three-dimensional) allow the creation of a web visualization of spatial data. Information can be viewed on different scales and overviews can be generated. In addition, the data can be stored sustainably, transferred and accessed from any location.

As there is currently no database on brownfields and related relevant information such as location, size, type of industry or former use, ways must be found to collect this kind of data. The “Raum+”-method, developed by the Chair of Spatial Development at ETH Zurich, is a method for collecting spatial

information and creating regional and national overviews. This method is essentially concerned with the survey of settlement area reserves in Switzerland. From these overviews, "spatial development strategies and measures for mobilizing settlement area reserves can be developed in a targeted manner" (ETH Zurich, online). These data are collected jointly with cantonal and municipal representatives who have knowledge of the areas. (cf. ETH Zurich, online) This approach could also be applied to the survey of industrial brownfield sites. Who can be responsible for collecting the data is still open. Cooperation between municipalities, regions and federal states as well as planning experts will, however, be indispensable.

Based on these spatial overviews, key areas for the development of industrial landscapes can be identified. Large brownfield areas are quite easy to locate, but small, significant areas can also be identified through a comprehensive, nationwide data collection.

Architectural, urban design methods are suitable for the elaboration of development paths and scenarios after the identification of key areas. The resulting concrete and analyzable visions can be used to examine structural effects and their effects on the local, regional and supra-regional level.

By using the test design method (cf. ETH Zurich, 2013; Schnepper, 2012) and the current methods of future and scenario analysis (cf. Kosow & Gaßner, 2008), concrete and integrated approaches to settlement and infrastructure development and the associated design requirements can be developed. It is necessary to consider these development paths and scenarios on all spatial levels (from the building level to the supra-regional level). A purely superordinate consideration by the preparation of a spatial overview is not purposeful, it needs a concrete and detailed investigation of the local conditions, in order to be able to draw conclusions from the effect on superordinate levels.

1.3. Project overview

The project „trAILs – Alpine Industrial Landscapes Transformation“ is part of the INTERREG Alpine Space Programme 2014-2020 and co-funded by the European Union. The project concentrates on former productive landscapes in the Alps, understanding their ecologic, economic and social regeneration as key priorities for the sustainable development of the Alpine region. The project consortium, comprising academic partners from different universities and research institutions as well as local or regional development agencies from five different countries, aims to generate significant knowledge about Alpine industrial landscapes, and develops and tests concrete and transferable strategies for the transformation of these landscapes. The support of local and regional stakeholders and the active involvement of the local communities are essential for this process. The four pilot regions are Eisenerz in Austria, Borgo San Dalmazzo in Italy, L'Argentière la Bessée and La Roche de Rame in France and Tržič in Slovenia. (cf. trAILs 2018: online)

The paper focuses on the first project phase, where a first process for the development of a transformation strategy was set up and tested in the pilot region Eisenerz.

1.4. Case study region

The Austrian pilot region Eisenerz is a municipality in the northern part of the federal state of Styria. Eisenerz and nearby municipalities are part of the so-called “Styrian Iron Route” region, a region that has been characterised by mining and related industries for centuries. Mining traditions and montanhistorical heritage are of great importance and give the region its identity.

Eisenerz lies in a deep circular valley and is surrounded by the steep wooded slopes of the Eisenerzer Alps and the Hochschwab mountain range, which reach altitudes of approximately 2,200 meters (see Figure 1). The natural environment and landscape in the region have a high value and potential as touristic and local recreation area. A large part of the municipality is covered by nature and landscape protection areas.

Tourism is becoming an important economic sector in Eisenerz for the last years, as the municipality tries to find a new development focus beside the industrial sector. Especially close-to-nature and sports tourism such as hiking, mountain biking, climbing in summer or skiing and biathlon in winter find perfect conditions in Eisenerz.

As shown in Figure 3, the municipality can be reached from Graz via Leoben and Vordernberg, from Salzburg via Admont and Hieflau and from Linz via Hieflau. Difficult road conditions in winter mean that the town cannot always be reached via the southern mountain pass Präbichl. There is an existing railway infrastructure in the direction of Hieflau and further via the Ennstal to Linz, or via Liezen to Salzburg, which is only occasionally used for freight traffic. A rail connection for passenger service does not exist anymore.

The region has been subject to a large population decrease in recent decades as a result of the technological change in industry and various competitive disadvantages due to its peripheral location in alpine terrain. From the early 1970s until today, the municipality of Eisenerz lost two-thirds of its population. The emigration of well-known companies, a lack of education opportunities and jobs, as well as the poor accessibility of the town move especially the younger generations to leave their home. More than 40 percent of the remaining population are over 65 years old. What remains is a shrinking mining city that is struggling with vacancies in housing, trade and industry, the maintenance of social and technical infrastructure and with the preservation of their mining culture and heritage. The municipality has tried to tackle these challenges for many years. Currently a new development strategy and a mission statement are being elaborated.

The industrial pilot site Münichtal, see Figure 2, is located in the northeast of Eisenerz. The area has a size of approximately 150.000 square meters. Parts of the site are still in use by a metal recycling company, but most of the buildings are vacant. They used to be part of an iron blast furnace, a gas power station, an automotive glass factory and an aluminium recycling factory/smelter. Beside the mentioned problems the whole municipality and region has to face, the main challenges in the development of the site are the mix of old and new buildings and their strongly varying quality (some buildings are more than 100 years old with a high architectural value, but derelict, some are modern functional industrial halls). The mix of used and abandoned buildings and infrastructure as well as the complex ownership of the different plots and buildings on the site make a transformation additionally difficult.

(f.l.t.r.) Figure 1: view on Eisenerz and the Erzberg, source: Bwag/Wikimedia and Figure 2: view on the pilot site Münichtal, source: TU München, Udo Weilacher, 2019

2. Methodology

In the following, the applied procedure and the use of selected methods and tools are explained. It should be mentioned that it is not the application of a single method, but the combination of several methods, i.e. the application of a repertoire of methods, that is productive. This must be put together individually depending on the object of investigation and the interest in research (cf. Hübler 2005: 635).

The procedure is basically divided into four steps: the analysis, the formation of possible development paths, the stakeholder workshop with discussion of the proposed development paths and the subsequent development of planning recommendations for the Münichtal industrial area in Eisenerz.

The chosen procedure is a first process test, a kind of experiment, which was carried out in the pilot region Eisenerz. It can be adapted step by step for the other pilot regions if necessary. The aim of the project is to define an approach in all four pilot regions that is transferable to other industrial regions and should be able to contribute to the transformation of industrial brownfields.

2.1 Analysis

In order to get an impression of the local and regional conditions and to evaluate the situation in the pilot areas in a comprehensive way, the analysis covers environmental, social, economic and spatial issues. As a framework for these different analyses, a separate policy analysis is acquired. In detail, the following issues are addressed in the different analyses:

- the environmental analysis covers the analysis of the topographical situation, the landscape, the natural environment and the ecologic status of the brownfield site,
- the settlement analysis contains information about the settlement structure and the existing building stock, the protected and characteristic types of buildings,
- the mobility network analysis covers the analysis of the reachability, the traffic and transport network and the public transport services,
- the supply and disposal infrastructure is analysed through a description of the access to information and communication technology and energy infrastructure, water supply and disposal infrastructure,
- the socio-economic analysis deals with the demographic and economic characteristics as well as the qualitative valuation and perception of the industrial site by the local population and
- the policy analysis contains the evaluation of policy documents of different sectors and administrative levels with regard to their recommendations and strategies for the transformation of industrial brownfields.

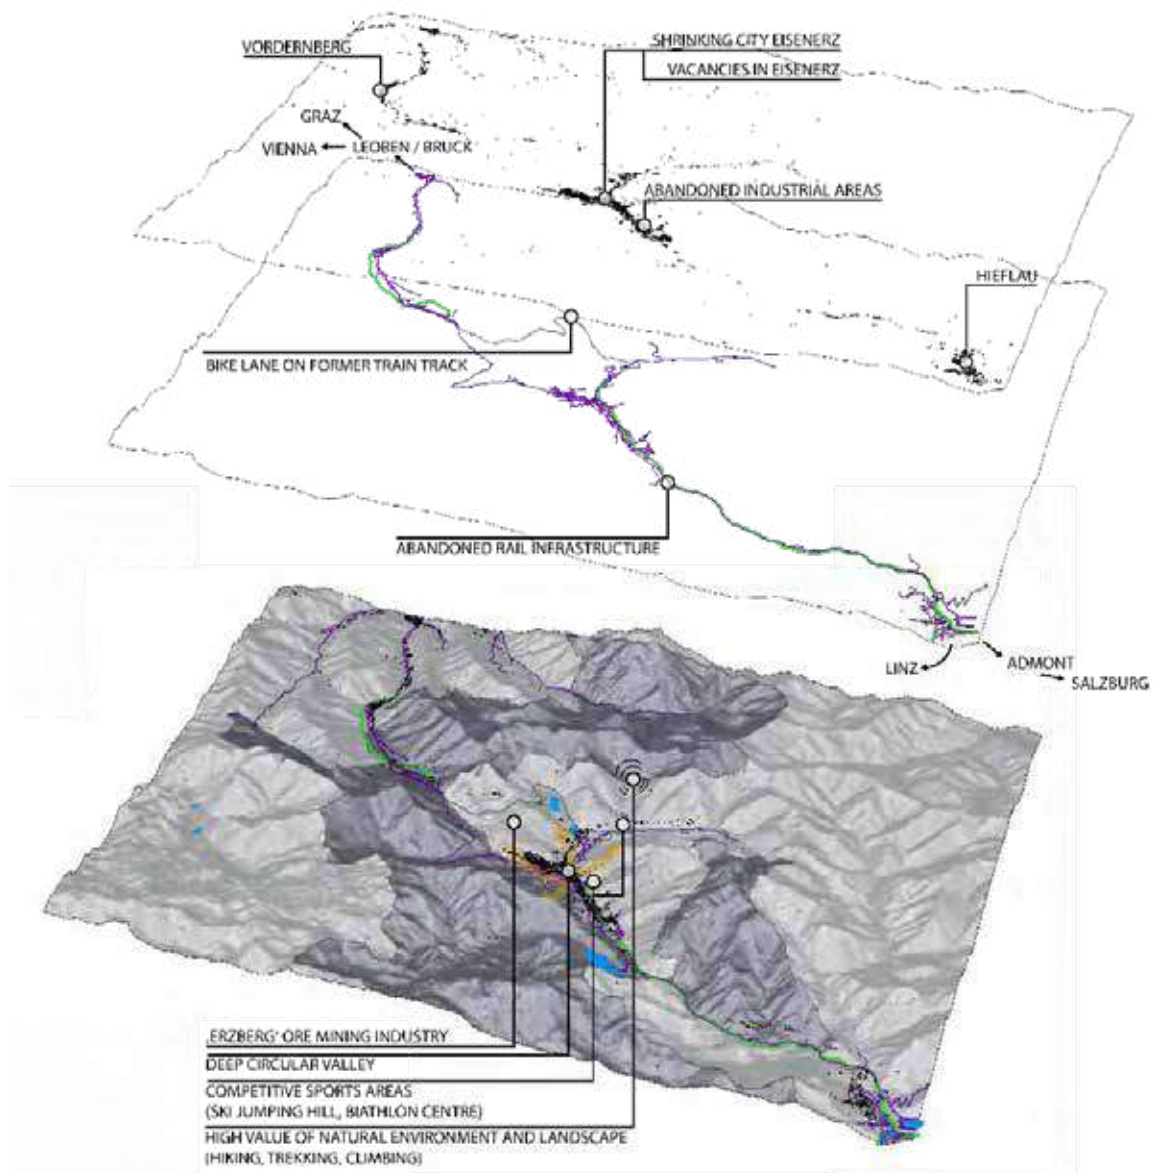

Figure 3: 3D-modelling as method for the spatial analysis showing the valley of Eisenerz and the main challenges, source: TU Wien, Julia Forster, 2019

Beside desk-research on the mentioned analysis topics, on-site research was essential for this first phase in order to experience the local and regional conditions and peculiarities with all senses. First impressions about possible strengths and weaknesses can be perceived, the contact to local or regional actors and the population can be produced and experiences in the participation in the life in the region can be collected. The project consortium visited the municipality Eisenerz and the pilot site Münichtal two times before the development of possible future pathways. Within these on-site researches, a first contact to local stakeholders has been established.

Qualitative interviews and discussion rounds, a visit of the buildings on the industrial site and a strolling around the town served to gather initial information. A photo and video documentation as well as 360° photographs were produced, to reflect and discuss the findings afterwards.

After the analysis of the different topics with various methods, the interdisciplinary team brought all the results together to find out the key problems and challenges (see Figure 3 and chapter 1.4). The project consortium established a first set of methods of different domains. This set should be transferable to all the other regions, but can be adapted in order to address the specific regional/local needs.

2.2 Building possible pathways for future development

Following the analysis phase, various development paths were developed for the Münichtal pilot area. After an initial brainstorming of the project team on possible future uses of the area, two main directions for transformation emerged - "de-construction" and "re-construction" (see Figure 4).

Figure 4: main directions "de-construction" and "re-construction" for the transformation of the site, source: TU Wien, Julia Forster, 2019

Figure 4 illustrates possible pathways within these two development directions for the pilot site in Eisenerz. A precise differentiation within these development directions is not possible. The elaborated pathways rather describe development approaches bridging, combining and interlinking the direction of deconstruction with the direction or single elements of reconstruction (e.g. soil remediation, planting, etc.).

The direction of deconstruction describes a stepwise dismantling of the existing building stock and uses. Thereby the quality of life of remaining residents as well as affordability are important markers for sustainable future developments.

The direction of reconstruction describes new usages and transformation of the existing building stock and the whole area. Possible resumption of former usages or completely new uses might include transformation and adaption as well as addition of buildings and building parts.

After this initial brainstorming and the elaboration of two basic directions of development, the different ideas generated were put into practice on several scale levels - at regional or municipal level, at pilot area level and at building level.

This multiscale approach was an important step in the idea generation process. It quickly became clear which possible future uses in the former industrial halls would be possible and for which the area and the halls are rather unsuitable. The comprehensive consideration made it possible to assess the effects of the future use ideas on the community and region.

The ideas ranged from cultural, tourist and industrial uses to unusual, utopian ideas for use. Here are a few examples: Use of the empty halls as film studios, as production halls for wood-based materials, as art and exhibition halls, as indoor sports centres, as apprentice training centers or as halls for urban farming.

Out of all these ideas and after several discussion rounds and under consideration of the analysis results to the local and regional circumstances, the project team decided to suggest three different pathways for a future development of the pilot site. Some important fundamental thoughts occurred:

- the usage of local and regional resources should be considered - usage of ore, wood, craftsmanship, knowledge
- a connection to the regional education and research cluster should be established to use local knowledge – the site could be a research and education spot with a special focus on product development, product testing and industrial fabrication; focus on special vocational education as complement to academic facilities in the region (Montanuniversität Leoben, FH Kapfenberg, TU Graz – important universities in Styria)
- a focus on processes, products and (local) materials should be given – e.g. processes/products related to ecological energy production, processes/products concerning the building industry,
- a focus on recycling is useful and beneficial - product life cycles, upcycling, re-use of materials within the existing abandoned building stock, research of building conservation technologies - using vacant local buildings as test area, a recycling company is already located on the site
- a focus on interdisciplinary collaboration can be an advantage – use of buildings as co-creation space, shared workspaces

Out of these fundamental thoughts, the mentioned three pathways have been elaborated:

Pathway “Back to nature”:

The photomontages (Figure 5 to 7) show a complete deconstruction of the area towards a near-natural use (meadow/pasture, forest).

Due to the infrastructure installed (pipes, canals) and the previous uses on the site, it can be assumed that extensive soil remediation measures would be necessary for these pathway. Figure 5 shows a variant, where only the buildings are dismantled, recycled and disposed. Existing infrastructures (pipelines, traffic routes) will be retained. Without further measures, the areas will be "reconquered" (within a few years) by pioneer plants.

Figure 6 and 7 show deconstruction variants aiming at a short- to medium-term agricultural or forestry use of the land. For this purpose, the technical infrastructure (pipes, traffic areas) must also be removed and the surface layer be replaced.

(f.l.t.r.) Figure 5: deconstruction with no further measures of renaturation, source: TU Wien, Julia Forster, 2019; Figure 6: deconstruction with renaturation - soil remediation - grassland, source: TU Wien, Julia Forster, 2019; Figure 7: deconstruction with renaturation - soil remediation - forest, source: TU Wien, Julia Forster, 2019

Pathway “Greenhouse”:

The pathway “Greenhouse” opposes shrinkage (in means of the shrinking city) with growth (in means of growing plants). The spacious hall areas on the site as well as good freight transport connections offer potentials for industrial plant breeding and sustainable ecological food production. For example, mushroom cultivation (with the local raw material wood as a carrier material), other fruit or vegetables as well as medical plants and herbs can be produced on an industrial scale. The spacious halls allow controlled conditions of growth and protection against intruders. The supply of water can be ensured via storage basins for slope and precipitation water.

Figure 8: pathway “Greenhouse” - usage of the industrial site as a place for growing plants, source: TU Wien, Julia Forster, 2019

The sewer system is designed for large flow rates. The controllable ventilation and lighting required for optimal growth and predictable harvesting is guaranteed by the existing electrical infrastructure supply. Figure 8 shows the spatial transformation and developments for the outlined approach of industrial agricultural use on the site.

Pathway “Recycling”:

The pathway “Recycling” introduces a new concept dealing with the city of Eisenerz as a living lab for building element recycling processes as well as new technical methodologies for the preservation and renewal of decayed or destroyed buildings (e.g. due to natural hazards). In close cooperation with regional research institutions, the regional construction and timber industries, a competence center and platform for deconstruction, recycling and re-utilization of buildings and settlement structures is elaborated. Figure 9 sketches a spatial concept of the transformation of the analyzed pilot site, creating the spatial environment for the research and industrial platform. Within the “Redesign Eisenerz” concept, a concept which deals with the deconstruction of residential buildings in the shrinking city, already mentioned spots of deconstruction become first living labs. So the city is understood as a source of raw materials as well as a test laboratory to develop procedures and methods for the recycling of building parts/buildings, for the repair of damp/damaged building materials and for the transformation of brownfield settlements into functioning spatial structures. Through these processes, a supra-regional showcase and competence center will be created, which will act as a trigger for sustainable regional value chain.

Figure 9: pathway “Recycling” - using the pilot site and the existing building stock in the city as living lab for research on the recycling of materials, source: TU Wien, Julia Forster, 2019

For the last two pathways, the conceptual integration of the existing institutions for vocational training, education and research within the region is essential for sustainable long-term development cycles. Therefore the existing resources of the region (raw materials, skilled workers, outputs and know-how of regional organizations) are further pathway- overarching drivers in strategic considerations and developments.

These three pathways/ideas for the brownfield transformation serve as a discussion base for the stakeholder workshop. The pathways should build a basis for the creation of new ideas. Topics can be added, combined or removed. The pathways should not be seen as project proposes, but should stimulate the discussion with the local stakeholders.

The approach of building different, in a sense also provocative or utopian pathways is an experimental approach. By testing and discussing the ideas and their advantages and disadvantages for the site, the municipality and the whole region, suitable transformation ways can be found or at least help to find a future direction.

2.3 Involvement of the stakeholders

As mentioned in chapter 2.1, some stakeholders have been involved in the development of the process already during the analysis phase to gain information about the local conditions and challenges in Eisenerz.

To involve the stakeholders more intensively in the development of a transformation process for industrial brownfields, the project team organized a stakeholder workshop in Eisenerz. Important local and regional actors from different professional fields have been invited - representatives of the municipality Eisenerz, owners of the different sections of the pilot site, representatives of the government of Styria, former workers of the site, local planners, regional development agencies, historians, local citizens and students and representatives of cultural and tourism associations. This interdisciplinary mix allows to gain information of various professional and personal backgrounds.

The stakeholder workshop took place in three rounds. The first round was a plenary session, where the stakeholders were introduced to the trAILS-project, the aims of the workshop and the suggested and elaborated transformation pathways.

The second round formed the core of the stakeholder workshop. The participating stakeholders were separated in three groups on three different tables. Each table had the same basic materials for discussion at disposal. The stakeholders have been separated by their professional background and their relation to each other and brought in their perspectives on the topic of industrial brownfields and the pilot site Mönichtal.

On each of the three tables the following main questions have been discussed:

- What do the stakeholders associate with the topic of industrial brownfields? Have they already dealt with industrial brownfields in their professional field?
- Which of the presented pathways were the stakeholders interested in? Which aspects did they like, which not? Which topics/issues did they miss?
- What are their own ideas for the transformation of the pilot site? Which impacts arise with these new ideas for the site, the municipality and the region? Which actors or organizations are needed for these new ideas? Which timeframe can be set for the implementation of the idea?

After the round-table session the participants came back to a plenary discussion, where all the findings and important aspects of the three tables have been presented. The discussion included important topics for the site and the municipality of Eisenerz, local stakeholders and citizens had the chance to talk to each other under the guidance of the project consortium. A fruitful discussion arose, and many of the participants got to know each other for the first time within this workshop - and this is one of the most important results - the “trAILS” project started a discussion process between local and regional stakeholders.

2.4 Planning recommendations

It turned out that the discussion groups on the three roundtables had different foci due to their professional field and interest. One group mainly dealt with the recycling pathway, one focused a bit more on a possible touristic and cultural use of the site, the third group discussed alternative industrial uses.

After a final discussion round the following ideas and aspects, independent from the preferred pathway, can be recommended for the transformation of the industrial brownfield test site in Eisenerz:

- the environmental and touristic compatibility and the ecologically and economically sustainability within the transformation process is the topmost priority
- the usage of local resources (ore, wood, space, natural environment, knowledge) should be forced

- the diversification of economy is necessary - not only looking for big companies like in past days, but trying to attract small and medium sized enterprises can be useful
- the transformation process has to be seen as a long-term development, profits will happen at different times (maybe not in the first years, but after some time the transformation projects can bring profit)
- the unique selling point is the size of the site - the large halls can be attractive for uses that need much space
- a combination of different pathways was seen as good way for a future development - e.g. deconstruct and renature parts of the site, new use for the remaining parts; combine small cultural uses with focus on industrial heritage and industrial use; mix different sectors
- research and education institutions should be seen as an important resource and actor, all kind of future uses can be linked to education (life-long-learning)
- elaborating an investor-brochure was seen as an essential step - the site and the vacant halls need a good marketing strategy and advertisement to call the investors' attention
- an awareness raising process for the local community has to attend the transformation process, only then the acceptability of the inhabitants will be ensured
- thinking of deconstructing parts of the site should be allowed (deconstruction is often seen as the worst-case scenario), because not everything can be preserved for the future - but, characteristic and unique structures should be preserved as they propose a great potential of the municipality/region and give the place its identity
- because of the huge number of owners, it needs a provider or an operator on the site, somebody who coordinates the different actions on the site (umbrella organization)
- the municipality needs an official pathway (currently they develop one) - this clear direction will be helpful for the transformation process too

3. Conclusion and prospects

Some elements of this first developed process turned out as very useful and expedient for the project aim and can be transferred to the other pilot regions.

The set of analysis methods of different domains was useful to get a holistic view of the problems and potentials of the pilot region and site. Different analogue and digital tools have been applied - e.g. statistic data analysis, qualitative interviews, GIS based spatial analysis, 3D-visualizing and -modelling - by using different format for processing the results (words, images, numbers). The on-site research was probably the most important step in this analysis phase. Suitable transformation ideas can only be elaborated after getting to know the local conditions with all senses. A multiscale view on the problems, challenges and potentials is essential to elaborate sustainable and useful transformation ideas. Designing these ideas and concepts can be seen as an essential step in the process - due to this communication base concrete discussion results can be gained.

Many of the analysis elements (see chapter 2.1) can be analyzed in the other pilot regions as well. Due to the interdisciplinary approach a holistic and integrated view on the potentials and problems on various scale levels can be generated. Stakeholders often have just one specific view or interest on the transformation possibilities - investors and owners concentrate on an economically efficient way, the municipality tries to integrate the site transformation in the development concept of the whole municipality, inhabitants have many different ideas but not always the appropriate information about the site. These perspectives can be brought together in an interdisciplinary workshop, like the "trAILS" project has shown. With the expertise of the project consortium and the knowledge of the local and regional stakeholders the necessary information for starting a transformation process can be collected.

It is very important to involve the stakeholders as early as possible in the process. Only then the local actors can prepare themselves for discussing about the topic of industrial brownfields, as most of them do not directly deal with this issue in their daily professional life. The participants of the process have to

be as open-minded as possible and should try to switch in other's perspectives and interests on the issue. It needs a lot of imaginative power to open to the different suggested pathways, as it is sometimes difficult to detach oneself from a worn image. The visualization of the pathways (see chapter 2.3) was a great help within this step.

The project consortium currently develops concrete planning recommendations for the pilot site Eisenerz. These recommendations should help the stakeholders to develop further transformation ideas and projects by assessing the most important information about the local and regional conditions and by using the resources of the newly established stakeholder network.

The described procedure is an iterative process and will be tested in the three other pilot regions of the project "trAILS" in the next one and a half years - always looking back to the previous processes and trying to learn from them and adapting the process components. Although the pilot regions are different in their local conditions and industrial uses, some key criteria can be identified. At the end of the project, a process should be set up, which helps municipalities and local stakeholders to deal with the transformation of industrial brownfields.

At the same time, a prototypical, web-based platform will be developed over the course of the project, in which the locations of the industrial brownfields can be represented on different scales by locating the pilot regions and areas in GIS, subsequently converting them into a geo-json file format and implementing them in the web environment. In addition, important analysis results and transformation ideas can be implemented in different formats (texts, images, numbers, tables or geo-objects in the web map). The platform is password protected and access can be granted at any time. This form of data storage is very sustainable as it is permanent, can be extended at any time and can be accessed from anywhere.

The developed process and the web-based platform should help municipalities and local/regional actors and interest groups on the one hand to deal with the transformation of brownfields and on the other hand to draw the attention of the federal and state governments to the topic of brownfield sites. The project shows how an overview of brownfield sites in Austria and the entire Alpine region can be established and how the necessary technical environment and relevant information can be developed.

The web-based presentation of results enables the transfer of the developed future pathways to other regions. This allows stakeholders in these regions to develop ideas and initiate discussion processes on the future use of brownfield sites too and enables a more sustainable use of industrial brownfield sites and the existing development structures in the sense of economically and ecologically sustainable development.

Let's Talk About Change

Experiences from a video exhibition confronting the public with urban and landscape transition by revisiting the original sites of relocated historical museums buildings to view these sites in their current state

Abstract

Between 1985 and 2015, settlement areas in the densely populated parts of Switzerland increased by almost one third. Whereas Switzerland still perceives itself as “Heidiland” (referring to Johanna Spyri’s novel), expected to attract tourists with its beautiful landscapes and charming small towns, the country has been transformed into an urban landscape dominated by conurbations. In the 2010s, several ground-breaking (direct democratic) popular initiatives linked to landscape issues were launched and received the majority of the vote. The will to control further expansion of settlement areas exists and the transformation of built heritage and landscapes is present on the national political stage, but the perception of change is still difficult to express. However, dealing with landscape transition and developing local planning concepts accepted by the people requires talking about change more site-specific.

In 2016, the authors organised an exhibition at the Swiss open-air museum Ballenberg. It presents more than 100 historical farm buildings from all over Switzerland, which had been relocated from their original sites for various reasons, from construction of new residential or commercial buildings to infrastructure projects, and original sites today cover urban, suburban and peripheral locations. Videos of the original sites of 14 selected Ballenberg buildings were produced in order to present these sites of origin as they appear today. The videos, which were presented in the respective museum buildings, confronted the visitors with the historical buildings – still in existence, but relocated – and the current condition of their former sites. A special visitor’s centre provided an opportunity to find out more and to discuss the topic of change with volunteers.

Experience gathered from this exhibition will be presented, giving an insight into the quality of the visitors’ debate initiated by the videos and reflecting on the impact of these findings in dealing with landscape transition in the future.

Introduction

Switzerland is a country rich of mountains, woods, valleys, lakes and rivers. The natural beauty of the landscape and its preservation became a national concern in the late 19th century, which was in line with a wider European movement. In the wake of the industrial revolution, in several European countries the awareness for the protection of historical sites and the conservation of landscapes was risen and finally several national associations were founded, for example in the United Kingdom the *National Trust for Places of Historic Interest or Natural Beauty* in 1895, in Germany *Bund Heimatschutz* in 1904, and in Switzerland *Schweizerische Vereinigung für Heimatschutz* in 1906. This international movement was linked to the new social class of intellectual bourgeoisie that distinguished itself through education in the humanities, literature and science, and was deeply rooted in the idea of the

Enlightenment. The awareness of the beauty and of the peculiarities of landscapes even became a means of identity formation on a regional and national level.

In 1881, Swiss author Johanna Spyri published her famous work of children's fiction *Heidi*, which not only became the fundament for a general Swiss Myth and was translated into many languages, but is strongly linked to this bourgeois movement of landscape conservation.

Switzerland is a comparatively small country within Europe with a comparatively high demographic dynamic, i.e. the total population has increased by 60% since 1960. Linked to the increase of the total population is an increase of settlement areas. In Switzerland, around 85 percent of the population lived in urban areas in 2015 and only 15 percent in rural areas (BfS 2014).

Land use in Switzerland is regularly surveyed by the national area statistics. The first survey took place between 1979 and 1985. Since then, two more surveys have been completed and a fourth survey is available in part. Between 1985 and 2009, settlement areas increased by 24%, increasing their share of the total area of Switzerland from 6.0% to 7.5% (Bundesamt für Statistik 2013). Between 1985 and 2015, settlement areas in the densely populated parts of Switzerland increased even by one third. The development of the settlement was closely linked to the expansion of the transport routes – and this was accompanied by the fragmentation of the landscape.

The separation of building zones and non-building zones (i.e. “landscape”) is one of the fundamental principles of spatial planning in Switzerland. One of the main aims of this separation is the protection of the landscape. The non-building zone is mainly the agricultural zone in which the production of food, but also biodiversity and recreation play an important role. Building permits in the agricultural zones (or more precise non-building zones) are subject to strict limitations, which are laid down in Article 28 of the Federal Planning Act. However, areas occupied by buildings in the non-building zones (i.e., agricultural zones or “landscape”) have increased by 21% throughout Switzerland over the past 25 years. The increase in area is due in particular to buildings linked to agricultural use (farm buildings) as well as detached and semi-detached houses. The number of dwellings in the non-building zones are highest in the rural communities. In the agricultural communities, every fourth dwelling is located in the non-building zones (Bundesamt für Raumentwicklung 2016). Today 590'000 buildings, i.e. 20% of all buildings in Switzerland, are located in the non-building zone. And, what farmers build, can look like an “industrial zone”: for example, large-scale glass houses, horse stables for horse pensions, silo installation. These figures demonstrate that landscape in Switzerland is under pressure. This situation is a result of, first, the fact that the federal planning act was not enacted until 1980, i.e. many buildings already existed when building in the non-building area was finally permitted on the federal level, and, second, the federal planning act has been amended and supplemented several times over the years, with the restrictive regulations being relaxed.

Traditional buildings in non-building zones, which are no longer used for agriculture today, are often very old. They bear witness to centuries of use and form an important part of the architectural heritage. They are of great importance not only for landscape aesthetics but also from a socio-economic point of view. There is currently discussion how heritage buildings could be converted to support the demographic and economic stability of eroding mountain regions (shrinking villages) without risking the loss of historical structures or negative impacts on the landscape (e.g., expansion of traffic infrastructure).

Moreover, urban densification, one of the main goals of Swiss spatial planning, is always linked to building new structures and, therefore, in urban environments affects built

heritage that carries specific information about the history of a location and thus strengthens the distinctiveness and the identity of a place.

Both aspects, i.e. transformation of built heritage in declining rural and built heritage under pressure in the context of urban densification are part of current debates.

Landscape, Landscape Protection and Swiss Identity

In his publication *Houses and Landscapes of Switzerland*, published in 1959, ethnologist Richard Weiss stated that the concept of landscape serves to "relate the village in its manifold ties to man and nature" (Weiss 2017: 316). Weiss regards man as a "cultural carrier and creator" and therefore distinguishes the natural landscape, which is untouched by man, from the cultural landscape, which was and is shaped by man. Already a decade earlier, Armin Meili, architect and pioneer of Swiss spatial planning, demanded in his 1945 publication *Zurich Today and Tomorrow*: "We don't want to let any crowding arise in our country. Switzerland should remain the home of personal freedom" (Meili 1945). Armin Meili's goal in spatial planning was the "decentralized metropolis". With this settlement strategy he wanted to counteract the unintended growth of few large cities. According to Armin Meili, the moderate further development of small and medium-sized towns and the construction of new settlement units separated by green corridors were intended to prevent the undesirable emergence of one huge urban area reaching from Lake Geneva in the west to Lake Constance in the east of the country. Journalist Rudolf Schilling (1975: 663) stated that the idea of landscape protection was of great importance for the development of Swiss federal spatial planning: "The impetus for federal spatial planning and with it landscape protection came from the affront to people's eyes".

In Switzerland, the protection of the landscape was a very early popular concern and in the beginning was mainly related to aesthetical and cultural reasons. In 1962, Swiss voters agreed on a federal constitutional amendment on the protection of natural and cultural heritage and only a few years later, in 1966, the respective act was brought into force. However, the constitutional amendment (1967) and the act (1980) on spatial planning followed comparatively late compared to other European countries because direct-democratic political processes delayed this very complex issue. During the decades of political struggles for a Swiss federal planning law, landscape protection was one of the main drivers in the political debate.

In 2007, a groundbreaking direct-democratic popular initiative was launched on the national level that was entitled *Landschaftsinitiative* (Popular initiative for the Landscape). The initiative answered nationwide protest that came up when in 2004 the authorities of the Canton of Fribourg had reclassified 55 hectares of farmland as an industrial zone in order to attract an US-biotechnology company. This decision by the government of the Canton of Fribourg, which was in conflict with the federal spatial planning law, brought the weakness of execution of legal planning instruments to the public's attention and resulted in a major nation-wide protest.

The initiators of this popular initiative wanted to limit the continuing urban sprawl in Switzerland, the destruction of the landscape and the resulting loss of cultivated land. This initiative dedicated to the protection of the landscape received major support by voters and finally forced the government to revise the then existing federal spatial planning law. This revised law was accepted by Swiss voters in spring 2013. With this revision the limits for further settlement development were appreciably strengthened. After decades of rising public concern on landscape protection – fuelled, among others, by the *Heidi* Myth – finally

public opinion and with it voters' concern on the protection of the Swiss landscape, on the prevention of uncontrolled extension of settlement areas and with it further deterioration of the remaining landscape, became a decisive factor for the future of Swiss spatial planning. Only one year before, in March 2012, Swiss voters had already imposed restrictions on the construction of second homes in Switzerland by voting in favour of the popular initiative entitled "Stop the Endless Construction of Second Homes" that limits the proportion of second homes in municipality to a maximum of 20%. As a result, municipalities (especially in the mountain regions) with more than 20% in second homes are not permitted to build new second homes. On 1 January 2016, the law on Second Homes entered into force. The main goal of this initiative was to prevent further loss of landscape.

In the Canton of Zurich, which is the economically strongest region in Switzerland, in June 2012 another popular initiative called „Kulturlandinitiative“ (Popular initiative for the protection of arable land) on the cantonal (not federal) was accepted. This initiative demanded that the agricultural land should be effectively protected by the canton in terms of total area and soil quality. Though this initiative was accepted by the voters in 2012, in 2016 voters rejected the revision of the Planning and Building Act (PBG) that would have been necessary to ensure that according to the aims of the „Kulturlandinitiative“ an equal area replacement had to take place when arable land is zoned into a building zone.

Again, in 2019 in a nation-wide popular initiative voters rejected the so-called „Zersiedelungsinitiative“ („sprawl initiative“). This initiative had aimed that for each new building zone elsewhere a piece of existing building zone of the same size has to be reclassified to an agricultural zone. Both government and parliament had opposed this initiative, arguing that the 2013 revised Spatial Planning Act already effectively limits further urban sprawl.

Meanwhile, in 2019 a new (second) Landschaftsinitiative (Popular initiative for the Landscape) is launched which again aims to protect landscape from further sprawl. To this end, clear regulations are to be anchored in the constitution. Within the zone reserved for agriculture, the number of buildings and the area occupied by them should not be allowed to increase any further. Construction of new buildings within this zone would thus have to be compensated by the demolition of other buildings.

The background of this second „landscape initiative“ (following the first that was launched in 2007 and that resulted in the 2013 revision of the federal planning act) is that this 2013 revision of the planning law postponed the subject of construction in the non-building zone (e.g. farm houses or glass houses for vegetables, but also horse boarding) to a later, further revision of the federal planning act. However, this second revision of the law has not yet taken place, and, therefore, several environmental associations have launched this second „Landschaftsinitiative“.

In sum, we can state that during the last 15 years Swiss people (respectively Swiss politics and voters) have launched a series of popular initiatives related to landscape protection and the prevention of further uncontrolled urban sprawl. As a result, landscape and heritage issues were very present in political debates and the media.

Perception of landscape in Switzerland

The 2013 study "New Approaches to the Assessment of Landscape Quality" (Bundesamt für Umwelt 2013) is part of the Swiss landscape monitoring program LABES and was conducted by the Swiss Federal Institute for Forest, Snow and Landscape Research (WSL). The landscape monitoring program LABES documents and assesses the state and development of the landscape in Switzerland using various quantitative indicators. These are based on a

comprehensive understanding of the landscape analog to the European Landscape Convention. The indicators therefore record landscape quality both in physical terms and in terms of public perception. The 2013 study is based on several indicators for the perception of the landscape by the population. We will refer here to three of these indicators: (1) "Peculiarity of the landscape" describes whether a landscape stands out from another in the perception of the population due to its specific character and whether a landscape is able to establish a reference to the past. (2) The indicator "fascination" describes the extent to which a person's attention is drawn to the countryside. Fascination contributes significantly to the attractiveness of a landscape, influences the length of stay of people in a landscape and is part of the recreational quality. (3) The indicator "authenticity" describes how landscape elements are judged to be appropriate to the site in terms of their authenticity, for example, regionally significant landscape elements (e.g. cultural monuments, waterfalls) or nationally important symbols (e.g. Matterhorn). For all three indicators, the assessment of the landscape by the population is more positive in the Alpine regions than it is both in the Italian-speaking southern part of Switzerland, which is dominated by narrow valleys with a high degree of urbanization and dense infrastructure networks, and the intensive urbanized Swiss Midland (*Mittelland*).

Magadinoebene, Ticino (Valley in the southern part of Switzerland), © ETH Bibliothek, Com_FC17-6512-001

In Switzerland, there are hardly any places that have not been altered in any way by people and in which no man-made buildings and structures can be seen. Most of these areas are located in the Alpine region. It is therefore not surprising that the perception of the landscape is most positive in the Alpine areas. More general and in line with this differentiation by regions, people who live in an agricultural area perceive the landscape of their own region most positively in comparison to residents of other types of communities. Due to the 2013 study by WSL rural communities are generally perceived as beautiful, and in terms of their complexity and authenticity they also perform well from the point of view of their inhabitants. The landscape is perceived most negatively in suburban areas, i.e. more negative in suburban than in urban areas (Bundesamt für Umwelt 2013).

Moreover, regions that consist of a high percentage of valuable landscapes that are listed in the Federal Inventory of Landscapes and Natural Monuments (BLN) are perceived more positive by its inhabitants than others. The Federal Inventory of Landscapes and Natural Monuments (BLN) describes the most valuable landscapes in Switzerland. Its aim is to preserve the diversity of Switzerland's landscapes and to ensure that the characteristic features of these landscapes are preserved. In these BLN areas, differentiated protection objectives aim the better consideration of nature and landscape values in the decision-making procedures on both the federal and cantonal level (Bundesamt für Umwelt 2013).

This 2013 study shows that the perception of the landscape is closely linked to references to the past and that regions or “landscapes” with high urbanization dynamics in recent decades are perceived negative by the inhabitants. Instead, areas which are classified as “deserving protection” and which are part of the national inventory of valuable landscapes exhibit an above-average positive perception.

Swiss Open-Air Museum Ballenberg and Swiss Landscape

In 1968, a foundation was established with the purpose to bring into existence and to operate a Swiss open-air museum. In 1978, the Swiss Open-Air Museum *Ballenberg* opened its doors and today presents 110 traditional rural buildings from all regions of Switzerland on an area of 66 hectares near the town of Interlaken. Most of the buildings are farm houses, but also stables, barns, blacksmith's shops, a cheese dairy, a brickyard, a sawmill, among others. These buildings that are built heritage are surrounded by vegetable gardens, meadows, pasture, and 250 farm animals ranging from rabbits to horses and oxen. Today the museum is a very popular destination for families, school children and tourists (with an average of 210,000 visitors per year, 20% of them tourists). Together, the 110 buildings and their surrounding are representing traditional Swiss landscape and Swiss built heritage. This museum is deeply rooted in Switzerland's national identity and is strongly linked to the *Heidi* myth.

All the 110 buildings in the *Ballenberg* museum used to be located in very different parts of Switzerland and found a new home in the open-air museum. At their original location, the museum buildings had to give way because their original location was used for new purposes and they had to give way to construction activities. A few of them very pro-actively collected in order to preserve them in the museum. Even though the reasons for moving the building to the museum are quite individual for each house, the *Ballenberg* houses have one thing in common: settlement change, landscape change and new economic activities (for example, industrial or commercial instead of agriculture, or new economic systems, e.g. milk pipeline to a dairy in the valley instead of alp cheese dairy) have left a deep mark on their “biographies”. Their continued existence in the *Ballenberg* museum is closely linked to the fact that the “face” of Switzerland has changed deeply since the end of the Second World War – and will continue to do so in the future.

In 2016 the museum presented as a special exhibition fourteen short films revisiting the original sites of fourteen selected *Ballenberg* buildings to see how these original locations look like today and why these buildings had to be moved from their original locations, providing an excellent illustration of how Swiss settlements have changed over the last fifty years. Both the idea for this exhibition and the implementation of the project came from the authors of this paper who also evaluated the response of the visitors.

The exhibition in 2016 presented the 14 films in the respective house or with an outdoor screen in front of the house if a presentation of the film inside the house was not possible. In the individual films, short sequences were also presented showing the building in its present state in the museum in order to create a recognition effect. The films were conceived in such a way that only original sounds from the original location could be heard, but no commentary. In this way, the films could be understood independently of the language of the viewers, and, as a side effect, the change of noise regimes (compared to the museum that does not allow motorized traffic) as urban location appear louder due to traffic noise). During the presentation of the films as the museum's annual theme for 2016, there was an educational center in the museum where all 14 films were available. In addition, a member

of the museum's staff was present for questions and discussions. In this center there was also additional material available for the 14 houses, which provided maps and pictures and also information about the current situation at the locations or the houses' history. Here, special educational material was also available for children and young people. The films have been included in the museum's permanent exhibition since 2019.

Finding the *Ballenberg* houses' home locations

At the beginning of the project there was the search for the exact former location of the 14 houses. The authors of this article carried out the search for the location and attended the video shooting and consulted the video production, i.e. they visited themselves all the original locations and therefore were able to analyze them with regard to the current state of affairs.

The shooting for the videos at the former locations of the *Ballenberg* houses was preceded by a site visit. Here planning documents and historical photos were helpful to find the *Ballenberg* house's original location. Not in all cases it was possible to determine the former location with the necessary precision based only on the museum archive's documents. This made it necessary to consult further historic references in order to determine the exact original location of the houses. This necessity resulted in an exciting search, which provided interesting insights. Historical aerial photographs were an important aid in this search. As revealing as the historical and current aerial photographs may be for capturing the spatial context and as helpful as they may be for determining the original location, they cannot replace the experience of immersing oneself in the site's reality.

The changes on site since the move of the respective *Ballenberg* house to the museum are particularly radical when it comes to the impact of new built transport infrastructure buildings. In these cases, the visible traces are usually extremely limited. No less than four of the 14 buildings had to give way to traffic infrastructures. For example, the farmhouse from Lancy (next to Geneva), which dates back to 1762. If it would still be in its place of origin, it would now be in the middle of a huge tram depot hall not far from the *Stade de Genève* (sports stadium in Geneva). A maze of highways, railway lines and parking lots hardly give any idea of what it looked like in this place when the *Ballenberg* house was still at home here.

Even in the case of the old forge from Bodio (Ticino, southern, Italian-speaking part of Switzerland), the construction work for AlpTransit's Gotthard base tunnel, a railway tunnel opened in 2016 with a length of 57 km (35.5 mi), has changed this part of the valley so much that no traces of the old blacksmith's workshop can be found. A new "landscape" has been created here dominated by the new railway control center of the south portal of AlpTransit. The Chiasso freight station has taken possession of the old home of the Novazzano estate, which was located here before, but meantime has moved to the museum. Where the building itself once was located, there is now a communal recycling center. Only a small trace remains, as the lowering of the curb still reveals the location of the former entrance to the main building of the agricultural estate. The changes that were caused by the widening of Klausenstrasse (leading to the Klausen mountain pass) in Spiringen that was demanded by modern motor traffic and led to the relocation of a hay barn to *Ballenberg* are comparatively small.

The role played by *Ballenberg* and its houses for Swiss identity is shown by the fact that a copy of a house relocated to *Ballenberg* was erected at the original location in 2 out of the 14 cases. Due to the area needed by the new use, the copies are not located at exactly the same location as the original, but a few meters apart. In addition, in both cases it is not a 100 percent reproduction that was created, but rather slight modifications that took account of their new use in the restoration. The replica of the rope factory Unteraegeri (Canton of Zug) serves as a bicycle shed of a condominium complex. The Wellhausen granary, which once had to make way for a new residential building, was rebuilt by a neighbouring hotel as a honeymoon suite. And while the granary moved to *Ballenberg*, the related mill building in Wellhausen, 200 m away, remained. In Rafz (north of Zurich) no copy was made after the removal of the historical saw building to *Ballenberg*, but today a car repair shop with the same building dimensions can be found here.

With the increase in population and the increasing use of living space per capita, many new residential buildings have been built in recent decades. These can be the replacement of existing residential buildings, but also the new construction of entire housing estates. In Meggen (near Lucerne), the stable barn from the early 16th century gave way to a single-family house area. In Richterswil (near Zurich) a multi-storey apartment building has been erected on the site of the winegrowers' house that was moved to *Ballenberg*. In Unteraegeri (Canton of Zug) where in former times the rope factory used to be, there is now a large condominium estate located very close to the city center. A inner-city housing estate with a total of 100 apartments was built on the former communal maintenance depot in Aarau, which was moved to *Ballenberg*. Here the fire brigade that was closely related to the moved communal maintenance depot is left on the neighbouring area – analogous to the mill building that remained though the granary left Wellhausen. The two latter examples in particular are an example of the aim of the revision of the Spatial Planning Act 2013 for urban densification.

The 110 houses of the Open-Air Museum *Ballenberg* uniquely link Switzerland today with Switzerland's heritage and history. They also provide a glimpse of tomorrow's Switzerland and invite visitors to reflect on building culture and settlement development. With the 14 *Ballenberg* houses and the associated 14 short videos, which show the current situation at the former location of the houses, the *Ballenberg* presents fourteen windows from the rural cultural landscape of represented by the *Ballenberg* museum into today's urban and suburban landscape of Switzerland,. This enables the visitors to directly experience the changes in settlement of the past decades. These windows sharpen the visitor's awareness of the ongoing dynamics of the built environment and built heritage and invite them to reflect on Switzerland's natural landscape, cultural landscape and urban landscape. In this way, the experience of both the landscape and the built heritage during the visit in the open-air museum is not a stand-alone experience, and is not finished when visitors' leave the museum, but by relating the *Ballenberg* houses to the current situation at the former locations the experience gained in the museum also retains its significance in the urban landscape perceived in everyday life.

Building in the museum or historic site	Current situation at the original location
	
Bodio TI – blacksmith's shop	railway control center AlpTransit
	
Aarau AG – communal maintenance depot	Bicycle shed in condominium
	
Unteraegeri ZG – rope factory	Bicycle shed in condominium
	
Brienz BE	
	
Champatsch GR – cheese dairy	Modern cheese dairy with milk pipeline
	
Malvaglia TI	

			
Meggen LU			
			
Novazzano TI		freight yard Chiasso	
			
Rafz ZH – sawmill		Car repair shop	
			
Richterswil ZH			
			
Therwil BL			
			
Wellhausen TG – granary		honeymoon suite	

	
Lancy GE – farm house	Tram depot and repair shop
	
Spirigen UR – barn	Enlarged road to the Klausen pass

Experiences with the museum visitors' perception of landscape and built heritage

In three steps, the response of the museum visitors to the presentation of the 14 films and the topic of landscape change and urban dynamics in the *Ballenberg* museum was evaluated. First, the experience of the museum guides who were in charge of the information center in the museum that presented all of the 14 videos, gave additional information and opportunity for discussion and, in addition, offered museum pedagogy related to the theme addressed by the videos was evaluated. Second, a questionnaire evaluation was used to learn more about visitors' assessment of the exhibition. Third, museum visitors were asked how they perceive Swiss landscape and how they assess the experience of the visit in the *Ballenberg* museum and the videos concerning landscape and built heritage.

When we asked Swiss visitors what landscape means to them, we received the following answers: "landscape means living space", "landscape is the basis for all living", "landscape means to recover from living in the city", "landscape means nature", "landscape means *Heimat*"¹, landscape means recreation", "landscape means fresh air, recreation and time-out". Asked about the impact of their visit in the museum on their perception of landscape and built heritage, they answered: "a visit to the museum sharpens your perception"; "after visiting the museum one notices that in former times the houses were much more embedded in the landscape"; "after a day at the museum, one sees many things differently in the landscape"; "one becomes aware of how the landscape used to be"; "the visit to the museum makes clear that in former times the landscape determined the buildings and that today a building is built and the location is adapted to the building"; "Swiss landscape is controlled by man. There is almost no place left that has not been shaped by man".

¹ There exists no exact English equivalent of the German word *Heimat*. *Heimat* is often translated by „home“ or „homeland“, but both English words do not reflect the aspects of familiarity with a space, of security in a space. To speak with Johanna Spyri's novel *Heidi*: Heidi's *Heimat* are the Swiss mountains. That is where the girl feels well whereas the foreign city of Frankfurt, where her aunt sent her, makes the girl feel sick, homesick. *Heimat* includes an aspect that is related also to identity and mentality.

One fifth spontaneously declared Switzerland as a beautiful landscape, one fifth spontaneously complained about urban sprawl and a deteriorated landscape and one fifth did both, i.e. praise the beauty of Swiss landscape and at the same time complain about urban sprawl. These numbers exhibit the ambiguities people have about Switzerland and its landscapes and built heritage: though the Heidi myth of Swiss beautiful landscape is still deeply rooted, people are concerned about urban dynamics that result in urban sprawl and increasing built-up areas.

The questionnaire, in addition, revealed that the immediate reaction of the visitors to the real built environment found at the houses' original location that was presented by the videos was: "terrible", "depressing", "that's a shame", "how sad to see this change", "what a contrast". One of the guides who was present at different houses during 2016 museum season reported that the impact of the videos was especially high for houses where the change was very massive, i.e. location of the farmhouse in Lancy that now holds the huge tram depot in the middle of multiple infrastructures or the location of the farm house in Novazzano that now holds the freight yard in Chiasso and the communal recycling center next to it. Both are cases where the "banality" of the new urban situation is very striking. More positive was the reaction to examples where inner-city housing was the succeeding use.

Museum guides who had been in charge at the information center in 2016 when the videos were displayed next to or in the museum houses reported that they had many discussions with visitors. Though the main purpose of the information center was to give further information to the theme of urban development and its impact of Swiss landscape and built environment, these discussions with visitors often became very political discussions. Some people even wanted to share their anger about urban sprawl and landscape change, and anger that was not provoked by the exhibition, but an anger they brought with them to the museum. In this cases guides just listened and did not start disputes, but they soon recognized that it was very appreciated by the visitors to be just listened to. Many visitors were especially interested in houses originating from their home region. Visitors that came from one the towns holding one of the 14 houses displayed in the videos were particularly interested in discussing the theme of change and in having additional information.

Conclusion

The protection of the landscape has a long tradition in Switzerland and a series of (direct democratic) popular initiatives concerning landscape protection issues occurred during the last decades. Public awareness of landscape change, but also concern about the built heritage, is therefore relatively high in Switzerland as political debates and the media have extendedly touched these issues. The study on landscape perception carried out in 2013 showed that in particular the inhabitants of suburban regions and the southern valleys (Ticino) that both exhibit urban sprawl view landscape and landscape change in their region very critically.

Reactions from visitors demonstrate that Swiss people are very ambiguous concerning the perception of Swiss landscape. They still praise the landscape's beauty, but at the same time they complain about its deterioration. It seems that the landscape's beauty as an asset of the nation and a main element of Swiss identity is deeply rooted, although the long discourse about landscape deterioration and urban sprawl that was intensified during the last 15 years due to a series of popular initiatives has left its marks.

Without doubt the confrontation of museum visitors with built heritage and today's state of the built environment by using 14 examples that could be experienced by real-world built heritage and videos presenting the real situation at the respective original locations drove people to debate and talk about the transformation of built environments. Especially in case where one of the 14 houses originated from their home region or home town, this talk about landscape and urban transformation was very intense. This talking about urban change was not limited to facts and figures, but included also emotions and even anger. This exhibits, that emotions are essential elements of the perception of the built environment, built heritage and landscape. The visitors' perception of landscape was not only limited to aesthetics, but the evaluation of visitors' response to the *Ballenberg* exhibition made obvious that their perception of landscape is very wide and includes also aspects like livelihood, joy, and identity.

The preservation of built heritage and landscape is a very complex issue that is difficult to perceive and to debate. However, talking about these issues is very essential for a deep involvement that is prerequisite for the further political debate. The evaluation of visitors' response to the *Ballenberg* exhibition has exhibited that real and well-presented example that are drawn from people's home town or home region, i.e. the environment that is very close to their daily life, provoke the most intense debates about heritage preservation and landscape protection.

The Influences and Implications of the European Capital of Culture on Intangible Heritage: Novi Sad 2021

Nebojša Čamprag¹, Aleksandra Stupar², Darko Polić³

¹Technical University of Darmstadt, Faculty of Architecture, Darmstadt, Germany, *camprag@stadt.tu-darmstadt.de*

²University of Belgrade - Faculty of Architecture, Belgrade, Serbia, *stupar@arh.bg.ac.rs*

³Urban Planning, Development and Research Centre - Urbanizam, Novi Sad, Serbia, *darko.polic@nsurbanizam.rs*

Abstract: As one of the most prestigious initiatives through which the European Union aims to promote richness and diversity of its cultures, the European Capital of Culture (ECoC) also holds an enormous potential for promoting urban regeneration and development. The aim of this paper is to examine the influences and implications of this program on the ways intangible heritage has been evaluated, treated and promoted. The focus is on Novi Sad, the capital of the Serbian province of Vojvodina, elected to be one of three ECoCs in 2021. Representing an example of transitional environment, it has experienced a shift from a socialist to a neo-liberal socio-economic framework that triggered a process of quasi-regeneration. However, during the bid for the ECoC title, urban heritage was (re)used as an important competitive advantage and local uniqueness. Both the Bid Book and implementation process have provided an interesting merging of tangible and intangible heritage, in which urban spaces will be used as a setting for promotion of urban brand through selected elements of intangible heritage. Consequently, the place identity was (re)created through images and narratives connected to European, national and local level, integrating place branding strategy, stakeholders (especially community) and urban policy.

Keywords: ECoC, heritage, regeneration, branding

Introduction

Since the launch of the program ‘World Decade on Culture and Development’ (1988-1998), the United Nations’ Educational, Scientific and Cultural Organization (UNESCO) started to strongly advocate for greater contribution of culture in national and international development policies. Along with the rising awareness of its development potential, the notion of cultural heritage considerably expanded in the following decades to encompass more than just monuments and the collection of objects. With the adoption of the ‘Convention for the Safeguarding of Intangible Cultural Heritage’ in 2003 (UNESCO, 2003), UNESCO divided heritage typologies on ‘tangible’ and so-called ‘intangible’

component, which assumes inherited traditions or living expressions, such as “oral traditions, performing arts, social practices, rituals, festive events, knowledge and practices concerning nature and the universe or the knowledge and skills to produce traditional crafts” (UNESCO, 2011: 3). However, contrary to clear division, cultural heritage remained characterized by deep-seated interdependence of its two major components, in which the fragile intangible cultural component became an increasingly important factor for maintaining cultural diversity and ensuring sustainable development in the face of growing globalization (UNESCO, 2003).

Being a supreme international body setting the standards in culture, UNESCO’s policies strongly influenced many other international institutions to start promoting similar initiatives. In 1985 the European Union (EU) responded to these emerging trends with the launch of the pilot project ‘European City of Culture’, transforming it to the project ‘European Capitals of Culture’ (ECoC) in 1999. Since then, more than 60 cities have held this prestigious title, which boosted their cultural, social and economic development. The title has also had a positive impact on the overall quality of life, strengthening the sense of community, attracting visitors and (re)gaining international recognition. During the recent years in particular, the increasingly competitive bid for the ECoC title initiated innovative and integrative approaches to both planning and policy-making of these challenging urban settings, influencing modifications of the outdated methods of heritage preservation, while stimulating public participation.

Due to numerous and diverse benefits triggered by the ECoC program, this European framework has become particularly interesting for urban governments in the formerly marginalized or disadvantaged contexts of ex-industrial and/or post-socialist cities, in need of thorough and effective restructuring. The focus of this paper is Novi Sad, the capital of the Serbian province of Vojvodina, whose identity represents an outcome of recent post-socialist, post-conflict and post-transitional turbulences. Following the fall of state socialism and the breakup of Yugoslavia, the hardships associated with internal conflicts and international isolation aggravated and postponed necessary socio-economic transformation, while international image and reputation of Novi Sad faced rapid deterioration. The conditions for re-inclusion of the city in international trends have been met only after the fall of the socialist regime in the year 2000, along with the shift towards the neo-liberal model of governance. However, planning practice, cultural management and heritage preservation remained characterized by a lack of transparency and quasi-regeneration that mostly aimed to satisfy the needs of the newly established real-estate market (Polić & Stupar, 2015).

The ECoC 2021 candidacy of Novi Sad represented the necessary trigger for reconsideration of its urban heritage as a competitive advantage, simultaneously enabling introduction of inclusive strategic governance on local level, as well as urban rebranding. This paper critically investigates the ways intangible heritage has been re-evaluated, treated and promoted during the drafting and implementation of the so-called Novi Sad European Capital of Culture 2021 project (NS 2021). The methodology relies on analysis of the objectives highlighted in the two most important strategic documents: the new Strategy of Cultural Development and the Bid Book for the ECoC 2021, along with the follow-up in the media and interviews with members of the Foundation Novi Sad 2021 - ECoC.

Novi Sad: Toward the European Capital of Culture 2021

As a response to growing constitutional crises during the recent decades, such as the Brexit or rising nationalist movements, the EU started to advocate for strengthening identification of its citizens through promoting the concept of ‘Europeanness’, which became profoundly present in the EU policy. The concept is based on various cultural instruments and cultural heritage, as a shared legacy of many European nations, aiming to strengthen the sense of communality, unity, and integration, but also for achieving greater cultural coherence (Lähdesmäki, 2014). It operates through the Creative Europe framework,¹ which encompasses some of the most prominent cultural events, e.g. European Heritage days, the European Heritage Label and the ECoC itself.

Along with stimulating the intensive interaction between built environment, historical values and local community, the ECoC program also aims at creating economic growth, encouraging urban regeneration and tourism development, building a sense of community, and developing European connections (European Commission, 2018). Due to a comprehensive set of objectives, it became of particular interest for the newly joined EU member states, burdened by the challenges of assimilation into the new socio-political, economic and cultural system. On the other hand, the ECoC program also gained on diversity, innovation and creativity. The City of Novi Sad, as the first representative of a non-EU country, was proclaimed an ECoC for 2021 during a particularly interesting selection process resulting with a shared title among three European cities for the very first time.² The bidding process led by the urban government of Novi Sad was equally particular. The adopted innovative governance approach assumed the development of the local concept and strategy for sustainable development of the cultural sector while simultaneously working on the candidacy for the ECoC 2021.

Looking upon the experiences of the former capitals of culture, the project NS 2021 was envisaged as the driver of local cultural and creative potentials for development, while fostering urban regeneration, improvement of the city’s international image and tourist offer. Such an approach required reconsideration, re-evaluation and an innovative treatment of intangible heritage, embedded in the new strategies of urban and cultural development. The outcome of these efforts ranged from the strengthening of institutions related to culture and heritage preservation, over the development of cultural and creative industries, the improvement of cultural participation, the decentralization of cooperation, to overall urban rebranding (Foundation NS 2021, 2016).

The context

Resulting from the specific socio-political circumstances, Novi Sad historically holds an outstanding importance in Serbian culture and national identification. It originates from the 18th and 19th century, when the present-day territory of Vojvodina was under Hungarian rule. Serbian immigration from the Ottoman territory to Hungary was encouraged by the special status of a recognized nation with extensive rights, in exchange for providing a border militia that could be mobilized against invaders

¹ Creative Europe is the European Commission's framework program with a budget of €1.46 billion for the years 2014-2020, aimed at supporting the culture and audiovisual sectors.

² Besides from Novi Sad, the ECoC 2021 was awarded to Elefsina (Greece) and Timisoara (Romania).

from the South. However, the absence of a national state during this period rendered Novi Sad to become a political and cultural centre of Serbian minority, labelled as “Serbian Athens” (Aleksov 2009: 277–278). Moreover, the city’s position as a strategic Habsburg military post (Figure 1) made it an important trading and manufacturing centre. The overall importance of Novi Sad further grew after Vojvodina’s unification with the Kingdom of Serbia in 1918, when it became the capital city of the multinational and multicultural province. The rapid industrialization and the rise of urban population started after its incorporation in the newly founded Socialist Federal Republic of Yugoslavia in 1945, when the city demonstrated a more radical urban development model in Central and Eastern Europe (CEE). However, progressive development of Novi Sad, along with a number of other Serbian cities, significantly slowed down during the last decade of the 20th century.

Figure 1.

For most of the countries and cities of post-socialist Europe, the period of extensive and highly dynamic processes of socio-spatial restructuring was the crucial for their free-market-oriented reforms (Stanilov, 2007). However, in addition to the breakup of Yugoslav Federation and the ethnic wars of the 1990s, Serbia was exposed to severe economic stagnation, international isolation and overall marginalization. Instead of dealing with the challenges of post-socialist transition, political elites in Serbia deliberately delayed socioeconomic reforms in order to keep their power (Vujović & Petrović, 2007). The legacy of the former technocratic planning principles thus long remained a dominant option for municipal governments, reflecting itself in rigid planning models (Vujošević & Nedović-Budić, 2006). For Novi Sad in particular, this was an equally difficult period that harmed its former reputation of an international centre of trade, manufacture, industry and culture. Being the second largest city in highly centralized independent Serbia, its urban development was overshadowed by the national capital Belgrade. Furthermore, the city also suffered major physical damage resulting from the NATO bombing campaign in 1999. Besides from human losses, several damaged residential neighbourhoods and the destruction of three iconic bridges over Danube, bombardment of the oil refinery caused severe pollution and widespread ecological damage (Figure 2). As a result, by the end of the 20th century, its international image was shattered by a plethora of socio-political and

economical problems resulting from a decade of wars and political instability, rapid deterioration of national economy, the legacy of autocratic planning and highly centralized political organization.

Figure 2.

NATO bombardment in 1999 left Novi Sad without its iconic bridges.

The later democratization of the country and the shift of national governance towards the EU integrations finally opened up some new development perspectives. With enactment of the Spatial Plan of the Republic of Serbia 2010-2020 (Ministry of Construction Transport and Infrastructure, 2016), polycentric model of urbanization and regional development policy has been introduced to the national policy framework. This strategy looked upon the dominant development trends of urbanization in Europe and finally improved the chances for balancing functional concentration between urban centres. However, considering that both decentralization and development are generally complex and time-consuming processes, local governance and planning of Novi Sad kept on relying on its already existing assets, such as culture and cultural production.

Cultural development strategy as a prerequisite for ECoC candidacy

Novi Sad became the national candidate for the ECoC title due to several very diverse reasons. First, the city has traditionally been characterized by its multi-ethnic structure comprising around fifteen ethnic groups besides the Serbian majority—Hungarians, Slovaks, Croats, Romani, Montenegrins, Rusyns, Romanians, Ukrainians, Germans and others. Second, the location of Novi Sad on the Danube River, only 70 kilometres northern from the capital Belgrade and its airport, provided many favourable opportunities for its accessibility, development and marketing (Figure 3). Finally, Novi Sad already had a long reputation as a national cultural centre—there are more than twenty active cultural and artistic societies, while the city also hosts a number of important cultural institutions, such as the oldest cultural-scientific institution of Serbia - Matica srpska, National Theatre, Museum of Vojvodina, Gallery of Matica Srpska etc. There is also a range of important cultural events, such as the Sterijino pozorje theatre festival, Zmaj Children Games, International Novi Sad Literature Festival, Novi Sad Jazz Festival, Festival of Street Musicians, and many others.

Figure 3.
Novi Sad: the panoramic view on the city from Petrovaradin Fortress.
Photo: Vervin, CC BY-SA 2.5.

In addition to a range of established cultural institutions and events, the city promoted a new, alternative approach to cultural development, especially after the fall of socialist regime and democratization of the country in the year 2000. The city's cultural and touristic offer has been radically modernized after the establishment of EXIT—a symbolically named cultural event triggered by a student movement that fought for democracy and freedom. Held at the prominent Petrovaradin Fortress (Figures 1 and 4), this event quickly became one of the biggest music summer festivals in Europe. Its official international recognition came with the title of the Best Major European Festival in 2014 and 2018, being one of the most prestigious festival awards in the world (EU Festival Awards, 2014). The skyrocketing success of EXIT has brought Novi Sad back in the international spotlight, causing major shifts in cultural and urban re-branding and marketing (Figure 4).

Figure 4.

Along with its strategic location and historic significance, a number of existing cultural assets and recent initiatives thus made Novi Sad to become national candidate for the ECoC 2021 bid. However, in order to become eligible contestant and to increase chances for winning, the city government

required a more comprehensive development approach, implying a new cultural development strategy that would comply with the complex EU requirements.

NS2021: a new approach to culture and cultural development

As a consequence of both foreign investments and the process of privatization during the immediate transition period after the year 2000, Novi Sad became exposed to a rapid commercialization of urban space and real estate development. The extremely neo-liberal investment climate initiated uncontrolled construction of collective residential units until 2008, jeopardizing spatial identity in some areas. The former planning framework was not capable of dealing with the needs of the emerging market, resulting with poor quality of urban design, and inconsistent and questionable construction principles, implemented without any consideration of environmental contexts (Balestrieri, 2013; Polić & Stupar, 2015). The shift of urban governance in Novi Sad towards a more systematic approach to urban development planning occurred only a decade after democratic changes. The enactment of the Economic Development Strategy in 2010 emphasized the need to attract more visitors and investors for the overall objective of repositioning the city in the international arena of free market economy (Local Economic Development Office, 2010). At the same time, the necessity of strategic planning in the area of cultural development was recognized. The rising influence of the City Council and the City Department for Culture in the local cultural policy management finally generated concrete aspirations toward the candidacy for the ECoC title. One of the major prerequisites for gaining this prestigious brand, however, assumed a local strategic document that would bring culture and urban development together (European Capital of Culture, 2016).

The procedure of drafting this strategic document was generally based on inclusive, integrative and democratic principles that regarded culture as a public property, with the right to culture assumed as one of the basic human rights. It involved an intensive participative process, which included a large number of administration departments, institutions, diverse civil and private organizations and informal groups. Series of presentations, discussions, and workshops were organized, aiming at achieving an equal representation of stakeholders included in the decision-making process. After the five-year long efforts, the Assembly of Novi Sad enacted the new Cultural Development Strategy for the period of 2016-2026 (City of Novi Sad, 2016), based on a synergy of local, national and EU policy-making levels. The highly diverse and comprehensive tasks spanned from the recognition of current problems, over the definition of directions and priorities, to the determination of implementation instruments and methods. However, what makes this strategic approach even more important is that the process of its elaboration has been conducted simultaneously and in accordance with the drafting of the so-called Bid Book for the ECoC candidacy (City of Novi Sad, 2015).

Although the heritage area of the traditional urban core was luckily spared of harmful interventions during the 2000s, the inherited values and continuity of urban historic areas of Novi Sad have been seriously affected, challenging the vital parts of its urban memory and uniqueness. Fortunately, the academic network of the University of Novi Sad, local NGOs, national minority associations and others timely recognized the importance of intangible heritage in the very early preparatory phases of the Bid Book for the NS 2021 program. Some small-scale research and projects have been conducted even before launching of the open call for the Bid Book, with a few of them later included in the draft. This approach was generally based on the premise that the urban identity and other intangible values should be preserved and emphasized as the reflection of the city's multinational, multicultural and

tolerant character, as well as its strong determination to embrace the future challenges of the 21st century (European Capital of Culture, 2016). Among the six strategic objectives of the strategy finally proposed by the Bid Book, most were focused on establishing participative cultural policy based on intercultural dialogue and internationalization, with a strong spatial reference. The sixth objective exclusively targeted promotion of cultural heritage, underlining the need of protection and inclusion of the public in revitalization process and (re)use. Cultural sector was thus envisioned as the central stage for propelling public participation, intercultural dialogue and cultural identity building, with the final aim to reinsert the city into wider cultural environments by redefining its identity within the challenges of transition, de-industrialization and post-war traumas. Finally, the new brand of Novi Sad was supposed to promote rising optimism, supported by the image of a hub based on services, innovations, software development, gaming industry and series of cultural activities.

The proposed artistic program was equally positioned at the intersection between urban tangible and intangible values, based around the idea of culture as a bridge between people and a reconnection with the specific historical and socio-political contexts. This topic came as a resonance to the historic bridges over the River Danube destroyed during the NATO bombing in 1999, although with a strong focus on reconciliation and reconnection. The central narrative of building bridges thus runs through the proposed artistic program of the strategy, conceptualized in four different groups, and pointing out to intangible cultural values to be preserved and further developed. The ‘New Way Bridge’ deals with the strengths of the city, such as its distinctive heritage and hospitality; the ‘Rainbow Bridge’ points to the city's weaknesses, such as reconciliation and migration, and search for the ways to meet these challenges. The ‘Freedom Bridge’ stresses the innovative potentials of the city, its young and creative industries, while the ‘Hope Bridge’ highlights the opportunities opening up through cultural facilities and public spaces (Foundation NS 2021, 2016). Within each of the ‘bridges’ were the major flagship projects that aimed at converting urban space into a stage for the active or passive brand promotion—e.g. the ‘Moba Project’ or the ‘Peace Chapel’.

The concept of the ‘Moba Project’ was based on participation and development of a sense of belonging, which connotes the volunteering actions of solidarity for revitalization and maintenance of public spaces, safeguarding of cultural heritage, planning and presenting cultural events in local neighbourhoods. The program also used a multifaceted strategy for the transformation of public spaces, used in the ‘Art in Public Space’ and the ‘Small Scale Urban Space’ projects. Additionally, the focus on heritage through the ‘Moba for Heritage’ introduces the idea of people working together on renovating traditional houses, as symbols of joint cultural heritage in multinational environment. It envisages the renovation of a German, a Hungarian, a Slovak, a Romanian and a Serbian house, as an act of enhancing social cohesion and intercultural cooperation (Foundation NS 2021, 2016). On the other hand, the project ‘Peace Chapel’ generally deals with the ideas of peace and reconciliation. As a public event outreaching international audience, the project envisaged use of urban space as a setting for establishing a dialog on the EU future. Urban space was also to be used as a stage for other events targeting international exchange, cooperation and promotion of diversity, such as ‘Bridging Barriers’, ‘Breed’, or ‘My Voice Travels’. Other targeted objectives were reconciliation (‘Fugitives’), collective memory (‘Brotherhood and Unity’; ‘Where were you when the bombing started?’), and (inter)cultural legacy and identity (‘At the Crossroads’; ‘Gastronomic Identity’).

A year after the ECoC title has been awarded, the projects such as ‘Heritage Walks’ and ‘Intellectual Topography’ were launched in 2017 and later developed in various urban neighbourhoods, including

different aspect and time spans of intangible heritage. ‘Heritage Walks’ have got a wider (European) dimension gaining the recognition of similar initiatives within the Faro Convention Network (European heritage community network), while the Association of Architects of Novi Sad (DaNS) initiated new topics focused on the heritage of the Modern Movement (‘Modern Architecture Walks’).

It is also important to notice that the link between intangible heritage and urban space transformations equally held a prominent role in the Bid Book. For example, the biggest cultural infrastructure project, focused on the conversion of a redundant metal factory to the creative urban district, was based on a narrative of a factory as a Chinese quarter, due to the use of abandoned buildings as warehouses for Chinese products during the 1990s. The ideas for its transformation have been developed and evaluated through round tables, documentary film production and numerous studies. The other significant example represents the refurbishment of the old Silk factory in the historic neighbourhood Almaški kraj. Nowadays, it is an active local cultural centre (‘station’) established through the mutual efforts of the Foundation and the association of ‘Almašani’.³ The activities of the association included collecting and presenting local oral traditions and a wide range of intangible heritage, while their contribution was officially acknowledged through the partnership in managing the programs of the ‘station’. Finally, the project of 46 urban pockets, focused on the redesign of small public spaces, also included collecting local intangible heritage, as a part of the competition announcement for the redesign of these places.

Challenges and advancements of the NS 2021 strategy

Following its submission and evaluation, the EC Selection Panel particularly appreciated the prime topics of the Bid Book, such as its diverse focus on inter-cultural dialogue, reconciliation and the art of peace (European Capital of Culture, 2016). Furthermore, its aims and objectives favourably reflected some of the most important international value frameworks in the field of cultural development by UN, UNESCO and ICOMOS (Foundation NS 2021, 2016). Following the decision for Novi Sad to become one of the ECoCs in 2016 (European Capital of Culture, 2016), the local government established the Foundation NS 2021 as a non-profit, voluntary and independent organization (Figure 5). Its aims were clearly set at the implementation of the strategy’s objectives through developing culture, protecting human and minority rights, promoting arts, democratic values, European integration and international cooperation and exchange (Cultural Center of Novi Sad, 2016). However, the Foundation was also facing the challenge to deal with a number of limitations of the proposed strategy that the EU Selection Panel stressed out in its final report (European Capital of Culture, 2016). Among others, the narrow geographic spread of proposed partners, lack of elaborated audience development, and unclear ownership of the strategy within the city council were highlighted (European Capital of Culture, 2016). There was also a lack of the flagship projects, while the proposed aim at building trust and restoration of cooperation between the countries formerly at war was lacking on clear indications for reaching its key objectives. Finally, the bid also omitted integration of the cultural strategy with the city’s urban development plans, while at the same time suffering from an

³ The local community of the Almaš neighborhood.

underdeveloped legacy beyond the place-branding benefits of the ECoC brand (European Capital of Culture, 2016).

Considering a range of intangible socio-cultural values in the core of the NS 2021 program, reaching a high diversity of its objectives seemed to be a rather challenging task. Additionally, the cultural operators and institutions in Novi Sad generally lacked profound experience and expertise in cultural policy making and management (Tomka & Kisić, 2018). As a final result, the updated version of the Bid Book had very little in common with its earlier version, based on which the award has been made. It showed a number of ambiguous, overstated and conflicting views on many of its integral aspects, generally ranging from the approach to the city itself, over the motives behind the application, to the vision of cultural development and means of achieving this goal (European Capital of Culture, 2017; Tomka & Kisić, 2018). The lack of a clear artistic dimension and its general focus on festivals even threatened to harm the cultural quality and integrity of the overall initiative (European Commission, 2017; Jovanović, 2018). As a consequence, the new urban brand of Novi Sad has been promoted and elaborated by further development of the program Novi Sad 2021-ECoC, along with defining new artistic festival platforms, such as ‘Kaleidoscope of Culture’. The major focus of the Foundation’s management has therefore been placed to the shift from the regional brand of the EXIT music festival to some more advanced artistic concepts.

Contrary to a number of evident flaws, the NS 2021 strategy still provided a number of significant advancements;⁴ especially regarding the definition of new approaches towards cultural heritage and policymaking. Before the nomination, there were no underlying strategic documents to facilitate the

⁴ According to the report by the panel of independent experts from 2017 (European Commission, 2017), representatives of Novi Sad highlighted that since its designation as ECoC the city already benefitted from increasing investments and tourism flows. Besides, local government invested efforts to increase the participation and involvement of locals, which reached more than 2.000 citizens participating in a wide range of proposals for development of cultural and public spaces, along with development of volunteering platforms (Novi Sad 2021, 2019). The NS 2021 project has been declared of national significance, implying that culture finally became one of the priority topics, while there also seems to be an increased awareness about culture among economic stakeholders.

decision making process, which made the local cultural policy highly bureaucratized and extremely non-transparent. Following the appropriation of planning tools and the re-evaluation of built urban heritage, the new Cultural Development Strategy, along with the NS 2021 program, imposed necessary reconsideration of public participation, as well as of the role of cultural heritage in strategic planning for urban development. Furthermore, different levels of governance—from local and provincial to national and international—were brought together to cooperate on a single project, overlooked by a panel of independent experts nominated by the EU. The strategy thereby fostered inclusion of the extremely complex and diverse composition of stakeholders, addressed their conflicts and interest and advocated for more cooperation with other social activities—such as tourism, education, creative industry or urban planning. The entire approach was shaped by the locally specific issues, driven by the need for (re)creation of place identity through intervening on previously unequal approaches to cultural contents of minorities and marginalized groups, insufficient support to local creative work, or unsatisfactory presence of local artists and contents at international cultural scene. As particularly praised by the EU selection panel (European Capital of Culture, 2016), the comprehensive mapping of the cultural sector in the city was seen as a solid foundation for the implementation of the new cultural strategy and the ECoC program. Finally, one of the most important outcomes represented the reconsideration of urban heritage and its treatment as a competitive advantage, which ranged from the common reuse of formally protected buildings, over the renewal and reuse of utilitarian architecture, to the new interpretation of buildings, areas and urban spaces in promoting intangible heritage (Polić & Stupar, 2015). Therefore, the NS 2021 represents a significant shift away from the former authoritarian, discriminative and elitist approach to cultural policy-making and quasi-regeneration, and a more responsive approach towards achieving the goals of place re-branding and, thus, urban competitiveness.

Conclusions

In the light of increased globalization, the complex and chaotic nature of the processes behind cultural policy-making could be perceived as a growing and widespread phenomenon (Davies, 2016; Roberts, 2010; Tomka & Kisić, 2018). Taking in consideration a relatively particular case of Serbia, its cultural policy could be characterized by a relatively long period of general confusion, manifested by a deviation from the rational policy norm, as a direct consequence of transitioning state and a lack of democratic cultural system (Dukic Dojcinovic, 2003). It even became an instrument of political communication, along with the shift from the spheres of the state and its actors towards the objectives of political elite (Jevtovic, 2015). Although the project NS 2021 could not have stayed immune to some of these trends, influences, and deficiencies, it could be seen as a rather revolutionary endeavour, primarily due to its high level of innovation and inclusion of diverse stakeholders, jointly working on the first genuine effort for a long-term cultural planning in Serbia.

Particularly significant element associated with the NS 2021 project was modernization of national cultural policy-making through introduction of the EU procedures, expectations and ideals (Tomka & Kisić, 2018). Equally important was a holistic and integrative model of urban and cultural planning and development that the project NS 2021 strongly emphasized. However, in the core of this development strategy is profound reconsideration of cultural values for overall place (re)branding. Imposed by the bidding requirements, the new approach to intangible component of cultural heritage was turned into an asset for urban re-branding, as one of the prerequisites for repositioning in the arena of competitive cities. Creative merging of tangible and intangible components of cultural heritage

thereby turned urban spaces into settings for redefinition and promotion of a new urban brand. Furthermore, (re)created through images and narratives connected to European, national and local levels, and subordinated to the values in the core of the ECoC policy, the emerging urban brand integrated the objectives of the place branding strategy, the stakeholders (especially community) and the urban policy. Therefore, it finally demonstrated the real capacity of intangible urban heritage to launch marginalised communities in the arena of competitive cities. Such an approach to recreation of place identity through reconsideration and enrichment of the core cultural values, while taking in consideration the voice of the local community, qualifies the NS 2021 program as a promising model toward reaching the objectives of urban sustainability.

URBAN DESIGN METHODS OF SHANGHAI TILANQIAO HISTORIC DISTRICT

UNDER THE BACKGROUND OF URBAN RENEWAL

ID 1424 Sun Xinyu College of Architecture and Urban Planning, Tongji University

Abstract :

The Shanghai Tilanqiao Historic District is one of the Shanghai Historical Scenery Reserve area, with Lane as the main building type in this district. Lane is one of the symbolic representations of Shanghai culture, which records the historical information and cultural genes of the city, and is of great significance to the sense of home, identity and belonging of the citizens. With the development of Shanghai city, some Lane buildings in Tilanqiao Historic District have been demolished . In addition, in the lack of public space and living space, residents renovate and expand privately in order to improve living environment. In this condition, the integrity of the community is broken and community life is difficult to maintain. Based on theoretical research and field research, this paper analyzes the spatial characteristics from the aspects of texture, architectural space, street interface and public space, and sorts out the buildings in the Lanes by the typology method. In addition to strengthening the design of streets and public spaces, it attempts to explore the means of achieving functional replacement of old buildings and guiding the form and style of new buildings. Under the premise of protecting the original historical districts as much as possible, it try to reshape the vitality of the area and meet the living requirements of the original residents. The urban design methods explored in this paper are expected to provide useful

information for realizing the regional renewal construction, and play a guiding and indispensable role in urban transformation, maintaining regional vitality, and retaining urban memory.

Keywords:

Historic district, Lane, urban memory, Urban renewal, Urban design methods

The scope of this study is located in the Tilanqiao area of Hongkou District, Shanghai. It was once under the jurisdiction of the former US Concession (later renamed the public concession) and was used by Jewish refuge during the Anti-Japanese War. It is also known as “Little Vienna” . The base is east to Baoding Road, west to Fair Road, south to Changyang Road and north to Zhoujiazui Road, with a total area of about 45.6hm² (Figure 1). In the

area, there are landmarks such as Xiahai Temple, Tilanqiao Prison and Xin'an Auditorium, and a relatively complete Lilong Building Group. With the development of the city, some of the houses in the Tilanqiao have been demolished, and the

Fig.1 Research area

residents have been privately remodeled and expanded due to the need of improvement of living environment. The integrity of the area is undergoing a broken process.

Tong Ming (2014) proposed that a dynamic city should have appropriate

density and scale, maintain sufficient diversity and mixing, and achieve rational organization of the city through multi-scale analysis of overlapping and effective connection of urban texture; Zhou Jian (2007) proposed to use the typology to analyze and study the urban design of Shanghai Old City to realize the reorganization of the spatial form of the block; Deng Hao et al. (2013) analyzed and interpreted the urban morphology through three basic characteristics : scale level, continuity and publicity, and presented the point that the spatial continuity and historical continuity of urban walking in the urban space is an important way to enhance the publicity and democracy of urban space.; Ding wowo (2000) studied the combination design and the group design of the new and old buildings in several cases to explore the basis and method of symbiosis. Yang Yimeng (2011) investigated the social interaction activities and distribution of Lane residents, and revealed the intrinsic relationship between the residential form and public space and people's social interaction activities.

1. Spatial Characteristics

There are some well-preserved lanes in the research area, and the texture of the street is relatively complete. Many modern architectural textures have been implanted around the city (Fig. 2, 3, Table 1). The roads in the range are roughly grid-like, the road spacing is between 150-300 meters, and the average land area is about 3-4 Hectare. As for the width of the road, the roads inside the study area such as Dongyuhang Road, Tangshan Road, Zhoushan Road and Changzhi Road are

narrow in width, generally 10-15 meters, which is in line with the old Shanghai renting (about 50 feet). This standard mainly responsible for life functions. The

Fig.2 Lane condition

Fig.3 Figure and ground

图例关系		
里弄住宅	双排	
	单排	
新式住宅		

Table1 Texture

Changyang Road and Zhoujiazui Road on the north and south sides are wider, and the width of the red line ranges from 30 to 50 meters, which mainly responsible for the traffic function (Fig. 4). The architectural form is dominated by the old lane, while modern architecture is less. The overall building density is high, and the height of the building is low. Among them, the houses in Lane are relatively short, mostly 2-3 layers, and the building

Fig.4 Road condition

density is large; the height of the newly built buildings are mostly 36-54 meters, and the building density is small (Figure 5). As for the street interface, due to the preservation of old Lane along Tangshan Road, Dongyuhang Road and Zhoushan

Road , the street appearance is more uniform, and the interface continuity is strong on these roads. On the side of the building, different forms of cross-street buildings constitute the characteristics of each Lane, forming a characteristic cultural landscape of old Shanghai. There are fewer public green spaces within the study area, the continuity of the street trees is not

Fig.5 Lane buildings and new buildings

strong, and the greening is seriously insufficient. Due to the high density of buildings and the crowded living environment, there are fewer places for people to interact and communicate, and public spaces are also seriously lacking.

2. Feature Analysis

2.1 Architectural features

The most important building within the scope of the study is the Lane Building. This kind of building is a product of the collision of Eastern and Western cultures and becomes a typical residence with Shanghai characteristics. The interior of the Lane in this study is basically a “fishbone” structure, with one main handle and few support, and the exterior adopts a continuous interface treatment to ensure the integrity and unity of the street facade. As a transition from public space to semi-private space, the cross-street buildings undertake more functions of communication activities. The small patios in front of the house implement the transition from semi-private space to private space.

2.2 The spatial scale and interface

The width of the road within the research area is basically between 10-15 meters. On the streets of Tangshan Road and Yuhang East Road , where the style is well preserved, the street aspect ratio is generally around 1:1, so the continuity and unity of the street are more strong and the space feels good. However, in the section of Anguo Road, the height of new buildings on both sides is more than 36 meters, and the aspect ratio of the streets is between 1:3-1:6 , so the street feels more depressed. On Kunming Road, the south side of the road is the 200-meter gray fence of the Tilanqiao prison, while on the north side is the combination of Lane buildings and 54-meter-high modern buildings. The disordered state and strong contrast of the interface on both sides make the street space's integrity seriously lacking, and the space experience is poor. (Figure 6).

Fig.6 Both sides of Kunming Road

2.3 Height characteristics

The height of the building is generally low in the study area. The high-rise buildings are gathering on the side of Changyang Road, and some of the lane buildings are inserted with high-rise residential buildings. High-rise buildings are mostly located at Baoding Road and Changyang Road, including the Hongkou District Health Building and the Dingli Building. And there are also many high-rise buildings on Anguo Road ,most of which are residential buildings and are more than

40m (Figure 7).

2.4 Building space combination

Some Lane buildings were demolished and new buildings were built in the inner part of the plot, and a combination of two or more different forms of buildings

Fig.7 Height partition

appeared in the same plot. In the current situation, there are problems such as poor connection of buildings, huge difference between old and new buildings, and high disparity in height. There is no good coordination and convergence between the old and the new.

2.5 public space

Since the Tilanqiao area is dominated by small-scale neighborhoods, with dense buildings and crowded environments, there is less public space for people to talk and interact. The daily communication space is mainly in the streets and narrow sidewalks, but there is no space for shading and rest on the sidewalks, so the active interactions are difficult to produce here. There is a street green space on the west side of Xiahai Temple. This small area where the elderly are active is already overcrowded, and the space is difficult to meet the needs of the surrounding residents.

3. Strategy

3.1 Strengthen the design of the street

On the road facilities, it is proposed to classify the streets in the area, and divide

Fig.10 (group diagram) Tangshan Road

Former

Later

Fig.11 (group diagram) Yuhangdong Road

Former

Later

Fig.12 (group diagram) Baoding Road

Former

Later

Fig.13 (group diagram) Anguo Road Renovation Proposal

When walking on Anguo Road, due to the over-height buildings of

Rongsheng and Jiulian Community, people feel pressure and tension in walking. Because the street aspect ratio is 1:3-1:6 there, which is far more than the aspect ratio of the comfortable street. It is recommended that the height of the new building be controlled between 10 and 24 meters, supplemented by specific

landscape or architectural design methods to cushion the suppressed space experience (Figure 13).

On the landmark street, as Kunming Road, the road sections are divided into three categories

Fig.14 Classification of Kunming Road Section

for control: perfect appearance section, transitional section, and the open space section (Figure 14). Considering that Xiahai Temple is the landmark building of the region, it is recommended to control the height and style of the building at the junction of Haimen Road and the section of Zhoushan Road when entering Kunming Road. Through different combinations of buildings, space can be retracted and people can be given the hint of entering a special space which can improve the landmark effect of the temple; at the intersection of Tangshan Road and Kunming Road, it is suggested to set up open space and create a landscape to attract people's attention and create a pleasant space experience for people. In front of the Rongsheng Apartment opposite the Tilankiao Prison, it is recommended to set up public spaces and green spaces, combined with the open rest area set by the bottom floor, to alleviate the heavy and monotonous feeling of the prison wall while buffering the negative feelings brought by the oversized apartment building. On the side of the Tilankiao prison, it is recommended to add a street tree or change the surface style of the wall to enrich the street landscape and reduce the

depression and heavy feeling of the current street.

3.2 Control the height of the building

For building height problems within the plot, it is recommended to take the height control of the streets and plots separately. Increase the height of buildings along both sides of Zhoujiazui Road and Changyang Road; retaining the original building height and control the height of Yuhang East Road, Tangshan Road and Zhoushan Road at 12 meters; limit the height of the remaining sections of the plot to 18 meters considering the width of the street and the coordination of the style. As for the internal height control, the height of the intact block is basically controlled at the height similar to that of the original. In the six sections on the north and south sides, considering the landmarks and other factors, the height control of the building is appropriately relaxed at 18 meters, 24 meters and 40 meters (Figure 15).

Fig.15 Height Control Advice

3.3 Increase public space

Considering the high density of land parcels, multi-node activity space is used instead of large groups, and more nodes are used to make social networks more dense, so as to promote the exchange of neighborhoods. On the street, it is by widening the sidewalks of the streets such as Zhoushan Road on Tangshan Road, and adding street furniture to provide a rest and cool space to improve public space;

considering the particularity of Lane buildings, the original layout of the building is changed, and some of the Lane buildings are enclosed to create public space which make contribution to the communication within the neighborhood (Figure 16).

Fig,16 Possibility Renovation of Lane

3.4 Coordinate new and old buildings

Currently most of the newly developed buildings in the existing plots are residential buildings. For newly built buildings, efforts should be made to achieve compact and continuous street interfaces, and to ensure the integrity of the streets as much as possible. It is recommended that the newly built buildings should be in harmony with the style of the old buildings, and the transition at the height of the building should be paid attention to,

such as increasing the construction of the podium to visually reduce the impact of the height difference on the

Fig.17 Add Podium

landscape (Figures 17).

3.5 small-scale acupuncture-style updates

For residential buildings with better status, the residential function can be extended, for the buildings that are not suitable for living , they are suggested to be reconstructed and replaced. For these buildings, it is encouraged to create various ways of upgrading without destroying the original texture. For example,

designing the variants of the original texture and performing isomorphic changes under the premise of ensuring similarity to realize diversity in unity.

Summary

This paper starts from the spatial characteristics of the Tilanqiao area, analyzes the problems from the aspects of characteristics of architecture, street interface, height, public space, etc., and then proposes strategies including controlling of building height, increasing public space, street classification design, acupuncture-style updating, etc. These measures are intended to reshape the vitality of the area and meet the needs of the original residents under the premise of protecting the original neighborhood as much as possible. The unique architecture and texture of the Tilanqiao area creates a unique style. Under the inevitable wave of urban renewal, we must consider the particularity of the area, consider the coordination and protection of the style, and preserve the unique memories of the city.

1_Transforming built heritage and landscapes

In support of global integrated landscape initiatives: Experiences from the Green Heart in the Netherlands

Alexandra Tisma¹ and Johan Meijer²

²*PBL Netherlands Environmental Assessment Agency, Johan.meijer@pbl.nl*

Abstract. Spatial planning is seen as an important instrument that could support the integrated landscape management (ILM) process. This paper presents the insights derived from important moments in spatial planning history, in the Netherlands, signifying that spatial planning consists of dynamic processes that anticipate and adapt to changes in society. The Green Heart is taken as an example of an integrated planning approach on a regional scale, which is appropriate for integrated landscape management (ILM). During the last 30 years since spatial planning in the Netherlands shifted from sectoral to integral, the role of the national government changed from blueprint planning to stimulating and facilitating planning processes of regional and local authorities. This has provided opportunities for multi-stakeholder platforms to effectively contribute to the spatial planning process. This paper elaborates positive and negative effects of those changes, providing insights in the form of lessons learned, which can be useful for planning processes of integrated landscape initiatives around the globe.

Key words: Landscape planning, integrated landscape management, Green Heart, Netherlands

1 Introduction

Integrated landscape management (ILM) is the process by which managers and stakeholders can plan, implement and monitor actions to support their objectives, including the Sustainable Development Goals (SDGs), on a workable scale. In ILM terms, a landscape is a socio-ecological system that is organised around a distinct ecological, historical, economic and socio-cultural identity (Denier, et al., 2015). Here, we therefore consider a landscape to be a manageable unit on a sub-national scale, such as a province, watershed or economic growth corridor, as on such a spatial scale, the SDGs can be integrated (Thaxton, et al., 2015). Hence, in the ILM approach, the word ‘landscape’ is used to describe a group of stakeholders or a partnership within a certain area — which is very different from what the term ‘landscape’ means in spatial planning.

ILM is suitable for situations of strong interaction between and interdependencies around natural resource use and management. This type of management is often initiated by nature and biodiversity protection organisations; which is why conservation, sustainable resource management, socio-economic development and restoration are integral parts of the ILM framework.

By focusing on multi-stakeholder partnerships, ILM also provides an effective form of collaboration and supports inclusive planning in cases where government capacity is underdeveloped, such as in developing countries. In most such cases, government policies alone cannot resolve trade-offs or mobilise synergies between goals. Stakeholders need to be directly involved in negotiations and commit to incorporating collaboratively agreed strategies and objectives into their own businesses and

programmes (Ros-Tonen et al., 2018). In a landscape approach, stakeholders thus aim to reconcile competing social, economic and environmental objectives.

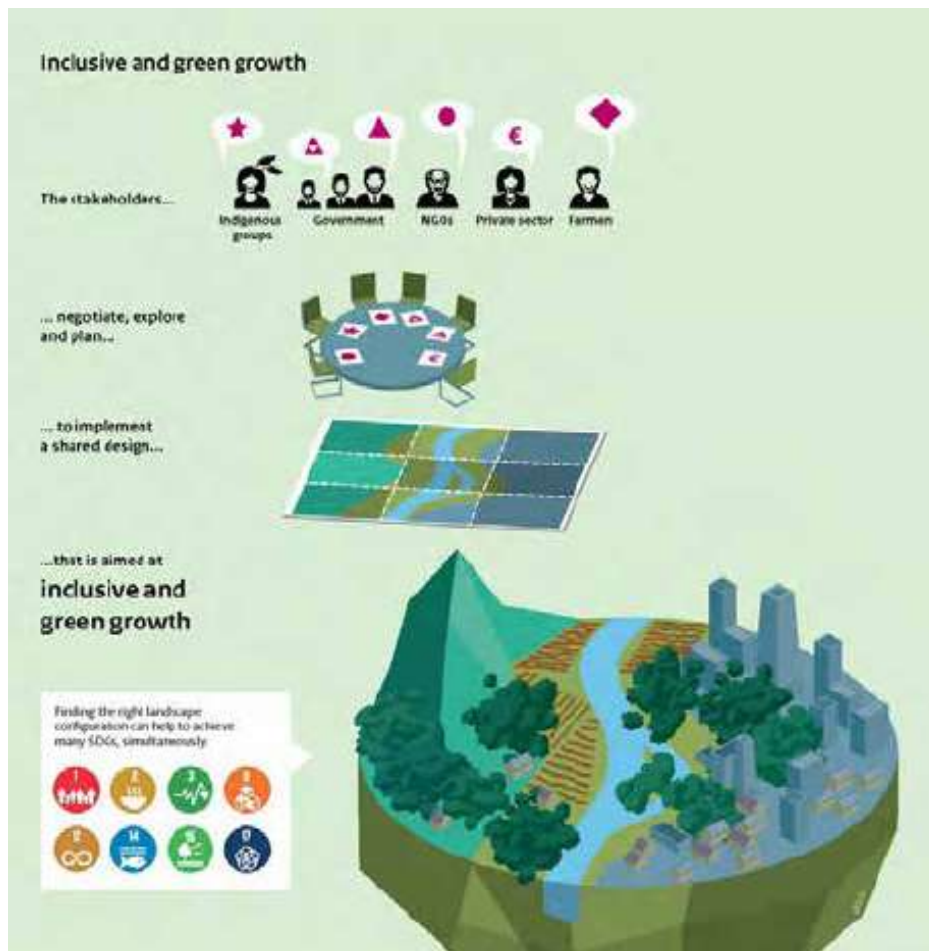

Figure 1. Inclusive green growth aims to achieve multiple sustainable development goals, simultaneously, by finding shared solutions on a landscape level (adapted from People and the Earth, PBL 2017).

Over the past two years, the Dutch Ministry of Foreign Affairs supported a project connected to landscape initiatives in Honduras, Ghana and Tanzania, in which PBL Netherlands Environmental Assessment Agency and EcoAgriculture Partners collaborated. The objective of the overall project was twofold:

- 1) to develop, apply and assess the use of spatially explicit modelling and scenario tools to help stakeholders in integrated landscape initiatives explore strategies aimed at achieving multiple SDGs;
- 2) to learn from the spatial planning experience in the Netherlands and related positive effects that can be achieved within ILM landscape initiatives.

This paper focuses on the second aim. We studied spatial planning in Netherlands using literature, map analyses and interviews. We zoomed in on the case of the Green Heart, because of its unique identity and location in the central part of the Netherlands, overlapping three provinces. This sub-national scale is well-suited for ILM studies, because it allows for stakeholders to more clearly understand the shared interests and impact of specific actions.

1.1 The Green Heart in brief

The Green Heart consists of a predominantly rural area between the four largest cities of the Netherlands (Amsterdam, The Hague, Rotterdam and Utrecht) that form a ring-shaped metropolis called the Randstad. To be clear, neither the Randstad nor the Green Heart are geographical names; therefore, they are usually not indicated on a map of the Netherlands. Both are concepts invented by planners.

Although the Netherlands is one of the most densely populated countries in the world, compared with other metropolises around the globe, Dutch cities are rather small (its capital, Amsterdam, roughly has 880.000 inhabitants). The Randstad concept, therefore, in addition to the spatial dimension, also — and much more importantly — has an economic element. By combining the populations and economic forces of the four cities and presenting the region as one large ‘city’, the government hoped to be giving the Randstad a prominent place on the map of Europe and make it economically competitive with other European regions.

The Green Heart was seen as an important contribution to quality of living in the densely populated urban part of the Randstad. In addition to its agricultural function, the Green Heart was also seen as a place of recreation for the Randstad’s inhabitants and of conservation of the green open space that is so characteristic of the Dutch polder landscape.

Figure 2. Impressions of the landscape of the Green Heart.

Source: PBL (upper and lower left); Natuurmonumenten, Ferry Siemensma (lower right)

The Green Heart covers an area of roughly 1,800 km². It is surrounded by the metropolitan areas of Amsterdam (to the north), The Hague (to the west), Rotterdam (to the south) and Utrecht (to the east). In January 2015, 726,541 people resided in one of the 40 Green Heart municipalities, which is a tenth of those living in the metropolitan part of the Randstad area. Today, the agricultural sector uses around

67% of the Green Heart's land area, with its revenues mainly coming from the production of dairy, forest plantations and horticultural products, the last mainly concentrated in and around the city of Boskoop. Ten per cent of the income of people in the Green Heart is being earned in such primary agriculture (Rabobank 2012). The proximity of Amsterdam Airport Schiphol and the Port of Rotterdam, in addition to processing and marketing centres as well as good road and rail infrastructure provide very favourable conditions for agricultural exports.

The Green Heart, similar to the rest of the Netherlands, is a man-made cultural landscape, mostly consisting of polders, below sea level (Figure 2). Seen from the air, it looks like a patchwork of pastures, interwoven with larger and smaller waterways and scattered small cities and villages. On closer inspection, it shows heterogeneity, made up of very different relatively old landscape types, the oldest of which dating back to medieval times (around AD 1100). The Green Heart is still rich in elements of cultural heritage. Especially in peat cultivation areas and along levees, where historical settlements are abundant, we can still find hundreds of well-preserved historical farmhouses. Windmills, sometimes grouped in clusters of three or more, arguably make up the most striking landmarks in the Green Heart, all of which have lost their original function as windpumps. In spite of urban developments in some of the areas over the past years, the Green Heart still looks like the archetypal Dutch landscape, calling to mind the landscape paintings by the old masters, such as Ruysdael and Van Goyen.

2 Spatial planning styles and the Green Heart

Spatial planning in the Netherlands has a long history and has undergone many transformations. In the years after the Second World War, planning involved a top-down, hierarchical perspective, with a focus on government-led land-use planning. This form of planning, which uses prohibitions, is called development control planning, with an emphasis on control (Van der Valk, 2010). Spatial plans of that period were considered blueprints. Most government authorities in the Netherlands, at that time, were organised according to individual sectors (e.g., agriculture, environment, rural development and water) and jurisdictions.

By the end of the 1980s, it was clear that the traditional practice of national government-led land-use planning no longer suited the forces of a fluid and mobile society. The national government, therefore, developed a more flexible development planning style (*onwikkelingsplanologie*). This planning style, although still containing many elements of hierarchical governance, was taking into account the dynamics within society, local implementation, attention for economics, citizen participation, more attention for concrete projects than for abstract plans, and the collaboration between public and private actors (Van der Valk, 2010).

During the 1990s, the role of provinces in policy-making and planning projects increased due to the decentralisation of responsibilities and tasks from the national to provincial government levels. The provinces started acting as mediators between national policy design and local policy implementation and gained a permanent role in planning projects crossing municipal borders. Provinces were actively involved in integrated planning processes, including strategic acquisition of land and high-risk investments in development projects (Van Straalen et al., 2015). Integration was expressed as the main objective, in order to guarantee the success of projects. But, as a result of economic setbacks at the beginning of the millennium, many of these projects have come to a standstill, mainly due to their large-scale, time-consuming, risky, and therefore costly character.

In 2006, the new National Policy Document on Spatial Planning (Nota Ruimte, 2006) was collaboratively published by four ministries and included the concept of integration as an objective of the national government (Ministry of Housing, Spatial Planning and the Environment, 2006). To

implement this objective, ‘integral spatial development’ was introduced as a new planning concept. The integral spatial development had to address several planning issues, including integration, transparency, openness, and participation (Louw et al., 2003; Boelens and Spit, 2006). Citizens, NGOs and market parties became increasingly involved in the planning processes, which gradually led to the practice of network-based governance.

The following sections show how these changes in spatial planning policy affected the Green Heart area.

2.1 Green Heart during the hierarchical planning period

It was during this period of spatial planning that the Green Heart was announced as an iconic Dutch landscape. Since the emergence of the concept of the Green Heart, policymakers, especially those at the former Ministry of Housing, Spatial Planning and the Environment (VROM), were eager to protect the area as a green open space for agriculture and recreation and prevent its further urbanisation. In 1999, the ministry published a report on the development programme for the national landscape of the Green Heart (*Ontwikkelingsprogramma nationaal landschap Groene Hart*), which painted an idyllic future for the Green Heart, where agriculture, nature, recreation and culture were in harmony and reinforcing each other. This political intention was repeated in the Fifth National Policy Document on Spatial Planning (*Vijfde Nota Ruimtelijke Ordening*, 2002). Gradually, the value of the Green Heart became broadly accepted in the society. In 2005, the Council for the Rural Area (*De Raad voor het Landelijk Gebied*), an advisory body of the government, placed the Green Heart along with eight other areas in the premier league of nationally important landscapes because of its rarity and importance for the national identity.

Over the course of time, economic development inevitably led to urban expansion, and threatened to fragment the Green Heart. To prevent this from happening, a series of national policies would lead to a seemingly vague limitation on the area allocated for urbanisation. But because of the large demand and scarcity of land for urban and economic expansion, it took years before the boundaries of the Green Heart were firmly delineated.

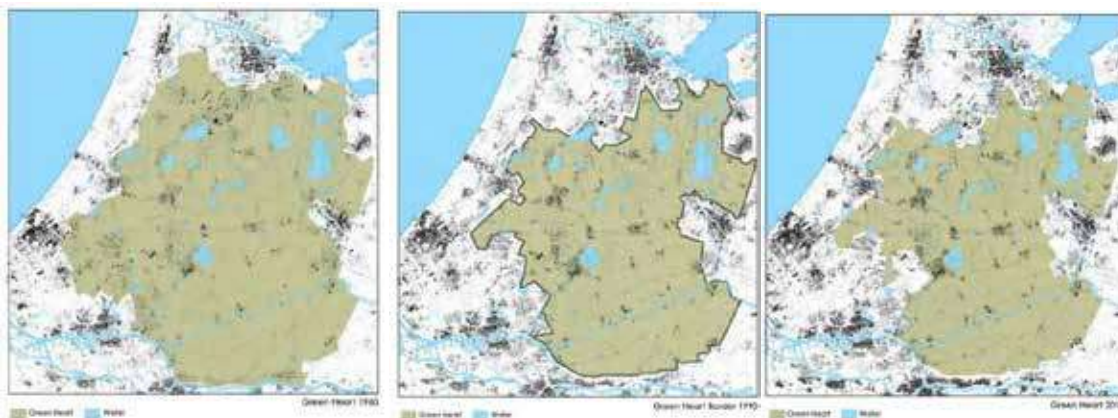

Figure 3. Changing boundaries of the Green Heart: a) indicative boundary; b) delineated boundary in 1990; c) indicative boundary 2017.

The boundaries of the Green Heart (Figure 3) were defined for the first time in 1990, in the Supplement to the Fourth National Policy Document on Spatial Planning (*Vierde Nota over de Ruimtelijke Ordening Extra, Vinex*), and elaborated in the National Structure Plan for Green Areas (*Structuurschema Groene Ruimte*), in 1992 (Kooij, 2010).

With the intention to maintain the openness of the Green Heart, the official Dutch policy, at the time, was threefold: (1) impose restrictions on residential and industrial development within the area; (2) provide alternative space for development in new towns and urban expansion outside the region; (3) improve the quality of landscape and nature within the area itself. For many decades, this combined policy strategy, in which restrictions were combined with development measures, was a successful approach for this vulnerable area. Over the course of time, the general tendency changed towards deregulation, decentralisation and privatisation. The national government dismissed the landscape protection policy and delegated those tasks to the provinces. As the Green Heart is situated in three provinces, this change threatened to reduce the Green Heart to what it had been before, in the 1960s, namely the hinterland of a number of individual cities and towns (Figure 4), each with its own development plans (Kooij, 2010).

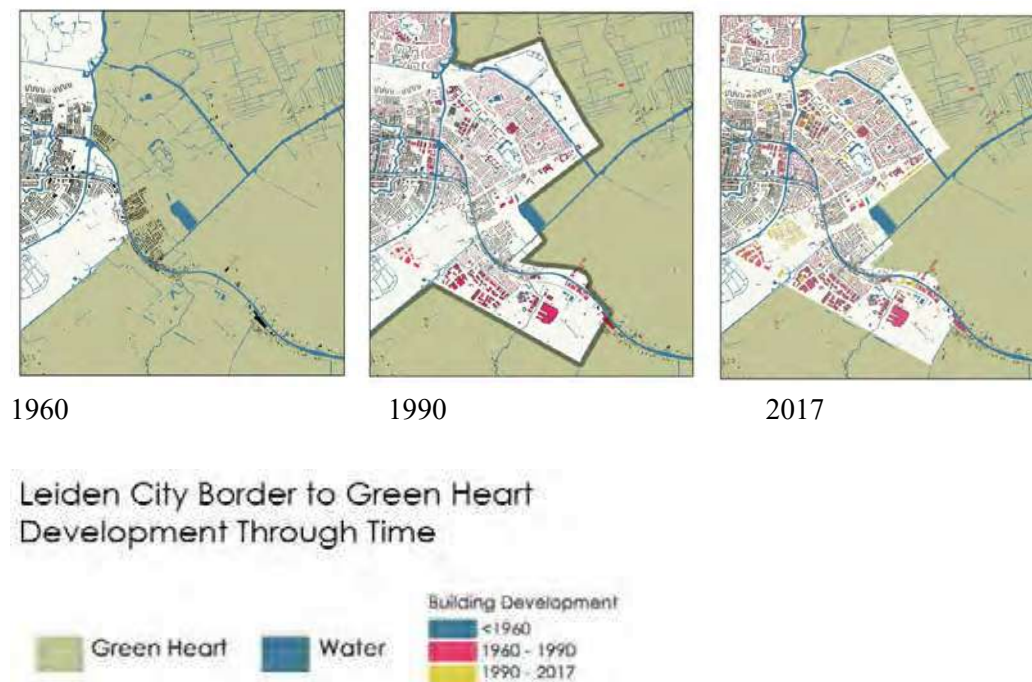

Figure 4. Urban expansion of the eastern side of Leiden, from 1960 to 2017.

Today, the average population density of the Green Heart is around 475 inhabitants per km², certainly not a figure that seems in line with the area's image of a non-urban, open landscape. The rapid growth in the surrounding new towns, however, suggests that the outcome could have been different if there was no policy, at all (Lorzing, 2004).

2.2 Green Heart in the network planning period

Since the beginning of this millennium, spatial policy has been shifting from control and restrictions to a network style of planning. The main consequence of this process was in 2012, when the national government stopped protecting the Green Heart as an important national landscape. The provinces, municipalities and organisations of the Green Heart region had to join forces and find a new way of protecting and promoting the region. This led to the establishment of several local organisations and two regional organisations (i.e. the Green Heart National Landscape and the Green Heart Foundation).

Green Heart National Landscape organisation was formed by the three provinces, five water boards and forty municipalities (Figure 5) with the goal to continue the balanced and coordinated development of the region as whole. The name Green Heart National Landscape was maintained and the Steering

Committee National Landscape Green Heart (*‘Stuurgroep Nationaal Landschap Groene Hart’*) was established (<http://stuurgroepgroenehart.nl/>). The Steering Committee focuses on achieving concrete results with 10 core projects on topics such as settling of peatlands, spatial quality and recreation. The Steering Committee supports the municipalities that take the lead in the promotion; for example, when drawing up plans for the future, generally through knowledge sharing, but sometimes also with financial means.

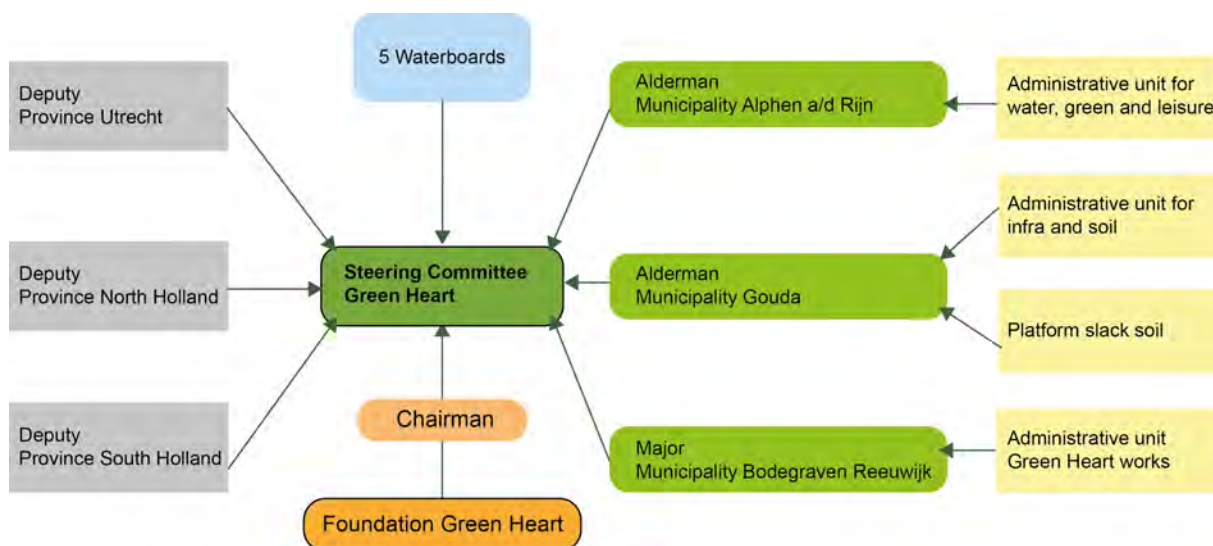

Figure 5. Organisation of the Steering Committee of the National Landscape Green Heart

The second regional organisation, the Green Heart Foundation (<https://groenehart.info/>), is a platform initiated by local agro-tourism organisations, entrepreneurs and farmers. The foundation has a general management, daily management with seven members, and advisory board consisting of ten members. Together with the private sector, NGOs, residents and local government authorities, the foundation counts 250 active rural entrepreneurs and more than 2,500 ‘friends of the Green Heart’.

The National Landscape Green Heart and the Green Heart Foundation collaborate on several levels, the most important common project being the Quality Atlas (www.kwaliteitsatlas.nl), which monitors the core qualities of the Green Heart. Next to those two regional organisations, there are several local organisations that cover various parts of the region and collaborate on certain subjects, such as nature development, landscape protection and healthy agricultural production (www.wijkenwouden.nl; www.vanade.nl; www.anv-santvoorde.nl; <https://anlvgeestgrond.nl/>). One of those organisations, the Green Clover (*De Groene Klaver*, www.degroeneklaver.nl), is described in the following section.

2.2.1 Local initiatives: The Green Clover Association

The Green Clover is a cooperative of several agricultural entrepreneurs that have joined hands with the aim of promoting their way of farming and nature conservation in the area around the city of Leiden. The cooperative encompasses both farmers, dairy producers and horticulturist. From their perspective, the interests of citizens and entrepreneurs, ecological and economic aspects, food and well-being should be equally represented in the landscape. In other words, their aim is to produce healthy food in a way that also benefits the environment. To this end, the association has engaged in several activities; it promotes green-blue services, nature and biodiversity protection and water management.

For the purposes of this study, we interviewed Theo van Leeuwen, chairman of the Green Clover Association and owner of the cheese producing farm De Vierhuizen in Zoeterwoude. Theo is the fifth generation to run this farm since 1800. We asked him about his farm and the association, his past experience with policy changes, and to synthesise his experience in a few messages that could be beneficial to stakeholders in similar landscape initiatives around the globe, for example, farmers in developing countries. This is what he said:

- There will always be farmers who are pioneers, farmers with a vision of change and progress, they take the initiative and others will follow their example.
- Especially in the beginning, the government should support such visions by providing subsidies and facilities, as well as by creating new supporting regulations.
- Various sectors should be treated equally to avoid one dominating the other.
- Combining several farms in an association has many benefits; it increases the range of products and the size of properties, contributing to the development of the whole region.
- Policy needs continuity, so that it cannot easily change the conditions of farming.
- Agreements need to be formally adopted in the long term, so that government changes, such as after general elections, do not influence the processes of cooperation.

2.3 Lessons learned from the Green Heart

The changes in spatial planning styles have left important marks on the Green Heart region as it is today. The period of hierarchical planning made the Green Heart an important area in the Netherlands. This long-term tradition has led to continuation of the protection of the Green Heart even after the national government decentralised spatial policy. Alternative ways of governance were established and many bottom-up initiatives emerged. This resulted in a complex and non-transparent situation, as many larger and smaller organisations supported by various stakeholders interact in the region. Sometimes they overlap and sometimes they have contradictory goals, but all of them in one or more ways aim to contribute to the economic, social and environmental quality of the Green Heart region.

What we can see from this case is the adaptability and flexibility that both entrepreneurs and the government are showing in times of change. Nowadays, active participation and bottom-up actions became a standard in the Green Heart, with many good examples to learn from.

3 Synergies between spatial planning and ILM

Similarly to spatial planning, ILM has many different approaches, entry points, and organisational models. What these have in common is an emphasis on achieving multiple social, economic and environmental objectives within the same large socio-ecological area (i.e. ‘landscape’) over the long term. The transition of spatial planning towards a local process that takes place within a network provides more and more opportunities for taking the specific interests of local stakeholders into account and to design plans that are tuned to the needs and circumstances of individual landscapes. With this transformation, responsibility gradually shifts towards regional and local actors. As illustrated in the previous section, stakeholders in the Green Heart have organized themselves in various connected platforms, in order to effectively influence and participate in the planning process.

This section discusses three potential synergies that could benefit both spatial planning and integrated landscape management — integration, spatial context and stakeholders involvement.

3.1 Aiming for integration

The key concept that connects spatial planning and ILM is that of integration. In general, this can be seen as the balancing of social, economic and environmental interests and objectives. That said, integration can be understood in many different ways; examples are the integration of stakeholders, initiatives or disciplines, or the vertical or horizontal integration of sectoral activities. Interviews with several stakeholders, conducted by Van Straalen (2012), showed that the meaning of integration differs between stakeholders involved in the same planning process or at the same planning level, which makes it more difficult for them to cooperate, integrate policies, or implement policies in an integrative manner.

Despite being complicated, planners and practitioners continue their dedication to integrating objectives and using an integrative planning approach in the Netherlands. In the new National Integrated Environmental Policy Strategy (NOVI), integration is also key, bringing spatial planning very close to the integrated landscape management philosophy.

Figure 6: Development Principle for an Integrated Environmental Policy Strategy (NOVI)

(Adapted by PBL from <http://mijnomgevingsvisie.nl/wp-content/uploads/2015/12/Werkwijze-Atelier-ZZ-Omgevingsvisie.jpeg>)

When looking at NOVI development principles, as shown on Figure 6, the ILM process cycle supporting Inclusive Green Growth (Figure 1) can easily be recognised. Spatial planning could potentially provide an important instrument to facilitate integrated landscape management.

3.2 Importance of local spatial context

One of the results from both ILM and SP is that of physical-territorial change of an area and its land use. When looking at the image on the bottom of Figure 1 and the far right image of the Figure 6, the end result of both SP and ILM processes looks very similar. Spatial impact is another common factor to be considered as a possibility to connect.

An example can be seen in integrated landscape development (*Integrale gebiedsontwikkeling*), a concept that has been used in Dutch spatial planning, over the past years. In integrated landscape development, parties such as provinces, water boards and project developers, are looking for ways to reinforce the various functions of a specific area, such as agriculture, nature, water and industry, with the use of various subsidies and regulations. The reason is often an assignment; elaboration of such an assignment can lead to improvement and/or more integral use of the other functions in nature.

How spatial planning affects space can be seen in the case of the Green Heart, described in the previous section. Another, recent and successful example of integrated landscape development is that of ‘Room for the River’, a flood-risk management programme that involves interventions at 30 locations. One of those is the “Room for the Waal” project in Nijmegen. It is one of the largest and most awe-inspiring projects realised within the framework of the Room for the River programme.

Figure 7. ‘Room for the Waal’ project by Nijmegen www.ruimtevoordewaal.nl/en/room-for-the-river-waal

The river Waal near Nijmegen has a sharp bend and a bottleneck. At high water, the river was unable to cope with the large volumes of water, causing flooding events in 1993 and 1995. To prevent this from happening again and in order to protect the city’s inhabitants against the water, the local levee was moved 300 metres inland and a four-kilometre-long secondary channel was dug. Fifty households had to be relocated as a result of these flood-risk management measures. This created an island in the Waal and a unique urban river park with many possibilities for recreation, culture, water and nature (Figure 7). Three new bridges connect the island to Nijmegen-Noord. The work was finished in the spring of 2016.

3.3 Stakeholder involvement

Integrated landscape management and spatial planning can be carried out in various ways and on various levels of participation. In the example of the Green Heart and Room for the River programme, both the national and provincial governments have taken the lead and sought support in the area.

In many other cases, plans are developed by public-private partnerships. The most bottom-up version of stakeholder involvement occurs in situations when local partners take the initiative and develop a plan which is afterwards supported by the government. In all such cases, recognition of each other's interests and the willingness to cooperate are crucial, and new solutions with broader support of the community can emerge.

The integral approach may entail extra costs, but could also result in many additional social benefits. Sometimes, it directly benefits the parties that are bearing the costs, but sometimes it also benefits others, or the benefits only become clear at some point in the future. This unequal distribution of benefits

is a known obstacle, which at times has resulted in desired combinations of functions not being realised. Formal ways of cooperation, negotiation, compensation and alternative financing constructions can sometimes remove this obstacle.

4 Conclusions

Finally, we can conclude that spatial planning is an important instrument that could support the process of integrated landscape management. Both spatial planning and ILM aim at integrated, combined and shared solutions. Integration, spatial impact, regional scale and stakeholders involvement are the factors that can bring ILM and spatial planning closer together. Similar to ILM, spatial planning nowadays involves various stakeholders who can sometimes have different visions and can see integration in many different ways; which is why integration can have various forms. Nevertheless, we should be aware that, although there are several synergies, there are substantial differences between spatial planning and ILM. ILM is a broad concept that acts in raising awareness, improving discussions and building partnerships. Spatial planning in the Netherlands, though, has long tradition and an established position, and it is supported by legal and financial instruments. In the Netherlands, government authorities are still the most important actors in spatial planning, as they play an important role in managing the competing claims on often scarce resources.

Long-term policy is another important issue in the Netherlands, from the point of view of spatial quality, economic stability and awareness rising. As the Green Heart example shows, strong and long-term policy made it possible for some of the Green Heart areas to develop and/or preserve quality. Long-term conservation policy raised the awareness about the value of the area among citizens and entrepreneurs. From the point of view of the local stakeholders, we learned that stable policy makes entrepreneurs feel economically safe.

From this, we can learn that landscape reconstruction, nature conservation and heritage protection, the goals behind the ILM, will only work within a framework of consistent, long-term policy and financial support, on a high administrative level. Creating an enabling environment that provides a level playing field for all stakeholders is considered yet another important role for government authorities on all levels.

These conditions are difficult to create, even in a country that is as developed and economically stable as the Netherlands. Even here, they only lasted for a certain period of time, and the changing political and economic contexts required finding other ways of dealing with competing interests. It is not very likely to expect that such conditions could be provided in economically less developed countries. There, an ILM approach that aims to find shared solutions seems more realistic. This requires local, regional and sometimes international negotiations between many different stakeholders, including farmers, NGOs, indigenous communities and different levels of government. As we can see from the example of the Green Heart, the multi-stakeholder platform Green Heart functions as an additional layer of governance in the management of the region. This example is fully in line with the ILM philosophy and shows the regional benefits of joined forces and shared responsibilities.

Built heritage and Agenda 2030. Embedding heritage values in the spatial planning local agenda.

Claudia Trillo

University of Salford, C.Trillo2@salford.ac.uk

Abstract: The UN Agenda 2030 is abundantly clear on the intertwined nature of sustainable development, as a combination of socio-economic and environmental aspects. Less explicit emphasis is posited on the role played by culture, identity and history and their contribution to pursue sustainable development. Indeed, the Sustainable Development Goal 11 encompasses strengthening efforts to protect and safeguard the world's cultural and natural heritage. This is measured by the total expenditure per capital on the preservation, protection and conservation of all cultural and natural heritage. However, successful heritage preservation and conservation strategies rest not only on capital investments, but most importantly on how they are embedded in the spatial planning procedures and instruments and on the level of protection they ensure to the existence of the built heritage as such. Failures in recognizing the existence value of heritage assets may cause significant flaws in the governance of preservation, particularly in growing urban areas under the pressure of the real estate market. This paper engages with the complex issue of embedding heritage values in spatial planning local agendas, by instrumentally discussing a purposely selected case study. It is suggested that although heritage values are socially constructed, still the intergenerational justice principle of sustainable development should urge for applying the precautionary principle while dealing with heritage assets, because of their non- replaceable nature. This paper concludes that the existence value of tangible heritage should be more explicitly recognized in Agenda 2030, by incorporating a target indicator allowing to track permanent loss of built heritage. Shifting from the international to the local scale, this paper also concludes that overreliance on the notion of spatial planning as political discourse may pave the way to slippery paths in heritage conservation policies, leading to the permanent loss of non-replaceable assets. It is anticipated that the paper concludes that local planning decisions on heritage conservation should be subjected to the precautionary principle and not being left into the political negotiation domain.

Keywords: built heritage, SDG11, Agenda 2030, spatial planning.

Introduction

Agenda 2030 recognized the notion of culture as ontological root of human identity and as driver for human-centred, inclusive and equitable development, by incorporating it in the newly reformulated paradigm for sustainable development and its articulation in the Sustainable Development Goals. UNESCO lauded as an unparalleled recognition the inclusion of culture within the international development agenda and the Sustainable Development Goals adopted in September 2015 by the United Nations. “The safeguarding and promotion of culture is an end in itself, and at the same time it contributes directly to many of the SDGs. Culture is who we are, and what shapes our identity. Placing culture at the heart of development policies is the only way to ensure a human-centred, inclusive and equitable development.” Heritage is mentioned in the Sustainable Development Goal 11, which encompasses strengthening efforts to protect and safeguard the world’s cultural and natural heritage. This is measured by the total expenditure per capital on the preservation, protection and conservation of all cultural and natural heritage (target 11.4.1: Total expenditure (public and private) per capita spent on the preservation, protection and conservation of all cultural and natural heritage, by type of heritage (cultural, natural, mixed and World Heritage Centre designation), level of government (national, regional and local/municipal), type of expenditure (operating expenditure/investment) and type of private funding (donations in kind, private non-profit sector and sponsorship)). This indicator is instrumental to measure the target 11.4 (Strengthen efforts to protect and safeguard the world’s cultural and natural heritage) and focuses on the capital investments on heritage, though it does not allow tracking the status of the heritage as such, meaning that the implementation of the Agenda 2030 in the local strategies would not necessary endorse the conservation of built heritage as such. The first part of this paper discusses how current perspectives on heritage values evaluation and the way it is conceptually incorporated within spatial planning practices, may undermine the principles of intergenerational justice and sustainable development. The paper concludes that the existence value of tangible heritage should be more explicitly recognized in Agenda 2030, by incorporating a target indicator allowing to track permanent loss of built heritage. This conclusion is achieved by discussing concepts such as heritage as social construct and participatory evaluation of heritage values. The second part of this paper shows how incorporating the heritage conservation and preservation policies within the conceptual framework of negotiable spatial planning policies and in the political local agenda may undermine the existence value of built heritage. The paper concludes that planning decision on heritage conservation should be subjected to the precautionary principle, because of the irreversibility of actions of destroying built heritage: indeed, whilst intangible heritage can be re-created, once lost tangible heritage is non-retrievable. This conclusion is achieved by discussing a purposely chosen case study, whose lessons can be extended to the larger international community of policy and decision makers, planners, conservationist architects and evaluators.

Heritage as social construct. Challenges to its evaluation in an intergenerational justice perspective

Being considered a pre-condition to successful globalization processes, heritage should be in itself an investment in the world’s future particularly in the local agendas. However, particularly in urban areas interested by rapid growth (United Nations, 2018) the combination of real estate marked pressures and shrinking public resources (Lobao et al., 2018) may induce local governments to prioritise short term local economic goals and immediate financial benefits, to catch up with the needs of a fast pace growing urban population. Because of its non-replaceable nature, heritage holds a specific existence value, benefitting future generations, which also makes its appraisal particularly challenging. Currently, there is a growing body of scholarship and international policies, which tend to emphasize the role of participatory approach on the evaluation of heritage. A review of the literature on evaluating citizen participation processes is conducted by Koorosha et al (2015), including criteria and measures used for such a purpose (Beierle, 1999; Beierle & Cayford, 2002; Bradbury, 1998; Charnley & Engelbert, 2005; Chess & Purcell, 1999; Edwards, Hindmarsh, Mercer, Bond, & Rowland, 2008; Rowe & Frewer, 2000, 2004). The appreciation of heritage values as socially constructed values implies a participatory and dynamic approach to the assessment, which requires methods and tools aimed at capturing them, including a robust and evidence- based stakeholders’ identification process. The Namur Declaration (EC 2015), for example, endorses the promotion of a shared and unifying approach to cultural heritage management, involving all the interested players and stakeholders. However, the adjustment of current evaluative methods and tools to

encapsulate in a systematic manner different viewpoint, is still to be achieved (Trillo & Petti, 2016). This gap is further exacerbated by the difficulties of encapsulating in the sustainability- oriented discourse the intergenerational justice principles.

Indeed, this trend on emphasizing the socially constructed nature of heritage is further sharpened by the shift from the materiality of the built heritage nature towards a more complex appreciation of its constitutional features. The concept of heritage as a product of intertwined tangible and intangible assets has gained international recognition and has been explicitly accepted in the global arena of stakeholders and experts. This shift from the original focus on the materiality of the heritage to a more holistic dimension challenges the traditional evaluation methods and approaches. The concept of tangible heritage is very well consolidated and spans from the individual building to its context. Since 1964, the Charter of Venice clarifies that conservation should encompass not only isolated buildings but also the whole setting: “historic monument is not only the single architectural work but also the urban or rural setting”. International organisations such as UNESCO and ICOMOS further reinforced this concept. In 1965 the Constitutive Assembly of ICOMOS defined as heritage both monuments and sites (art. 3.1): “The term monument shall include all real property, ... whether they contain buildings or not, having archaeological, architectural, historic or ethnographical interest and may include besides the furnishing preserved within them” instead “The term site shall be defined as a group of elements, either natural or man-made, or combinations of the two, which it is in the public interest to conserve”. The definition of monuments and sites was integrated in 1972 by the art 1.1 of the UNESCO’s World Heritage Convention with the third category of “groups of buildings”. In 1975 (Declaration of Amsterdam) the concept of heritage was expanded to embrace historic gardens, landscapes and environment. The 1987 ICOMOS Charter declared the importance of Conservation of Historic Towns and Urban Areas, while Urban Landscapes were incorporated in the possible heritage assets in 2005 (Vienna Memorandum).

Intangible heritage is a more recent concept, brought to the international attention of policy makers and decision makers only in 1994 with the Nara World Heritage Convention, which stated that “All cultures and societies are rooted in the particular forms and means of tangible and intangible expression which constitute their heritage, and these should be respected.” In 2001 the UNESCO adopted the Proclamation of Masterpieces of the Oral and Intangible Heritage of Humanity, establishing a list of such heritage. The inscription was based on the outstanding value acknowledged “from a historical, artistic, ethnological, sociological, anthropological, linguistic or literary point of view” (Vecco, 2010). Examples of tangible and intangible heritage are shown in Fig. 1 and 2.

Fig. 1-2. Examples of tangible and intangible heritage. Stonehenge. Guy Fakes night bonfire (Author’s photos)

The complex nature of heritage as underpinned in the current scholarship and international understanding, is also reflected in the growing importance that community and participation are gaining in the process for the definition of its significance. The revised Australia ICOMOS Burra Charter (ICOMOS 1999; original document: 1979) introduced the concept of “values-based conservation” and emphasized “significance” as community-based and contingent. The Burra Charter defines cultural significance as aesthetic, historic, scientific, social or spiritual value for past, present or future generations.

Defining value: origin of quality and kind of utility

In
her
(or

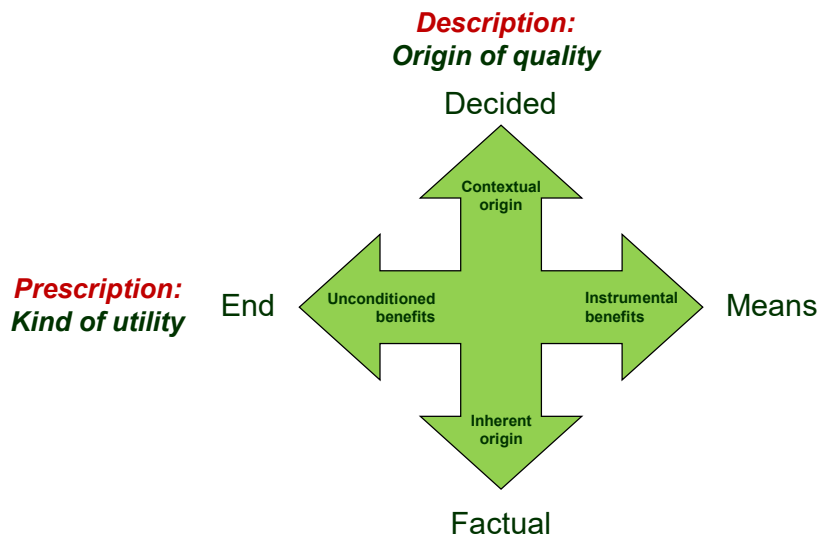

Figure 3. Conceptual framework for the appreciation of the heritage values (Source: Bengs, 2016)

In so doing, assessing the value of heritage is not a merely technical or operational issue (and as such, a problem of methods or tools), but requires a preliminary clarification of the philosophical stance underpinned in the evaluative object. Behind any assessment methodology or evaluative operational tool, the measurement of the value stems from an interpretivist paradigm, that is, who is / are the value givers and what does value mean to them. Traditionally, the evaluative methods for the appreciation of the value of the heritage can be grouped as follows: a) willingness to pay -including for example hedonic prices and travel costs- and b) Contingent Valuation; both can be successfully complemented with referenda, suitable to capture the political implications of the evaluation (Frey 1997). Traditional methodologies for the assessment of the value of heritage support the appraisal through the monetarization of the heritage as an asset for the economic system. This value can be either being captured within the real estate market as a reflection of the added value due to the presence of amenities, or calculated as the costs paid to reach a certain destination, or deducted from systematic surveys administered with a group of individuals (Throsby 1999 and 2001). Not quantifiable values such as the existence value are also a serious matter of concern (Throsby and Hutter 2008). In merely socio- economic terms, both tangible and intangible cultural heritage are considered a significant driving force in the European economy, society and culture, drawing from the rationale suggested by the EC (2015) and considering “Cultural Heritage ... as a special, but integral, component in the production of European GDP and innovation, its growth process, competitiveness and in the welfare of European society. Like environmental protection, it should be mainstreamed into policy and regarded as a production factor in economic and wider policy development”.

Re-casting the concept of heritage protection within the new international framework

More recently, the international debate around the value of cultural value has intensified. The concept of heritage has broadened into notions of local identity, belonging, nationalism, liveability of urban areas and social cohesion (Morais, & Chick, 2008; Jimura, 2015; YuPark, 2010, UNESCO, 2011). On 27th September 2016, the Mahdi's conviction (9 years) by the international criminal court because he helped to destroy shrines in Timbuktu (The New York Times, 2016). The trial was the first at the international criminal court to focus solely on cultural destruction as a war crime (The Guardian, 2016). The deliberate destruction of heritage has become a weapon of war, part of a broader strategy of cultural cleansing that includes murder and persecution of people in the short term, and the annihilation of identities and destruction of social fabric in the longer term. A sadly good example is represented by the deliberate destruction of the Buddas of Bamyán (Fig. 4).

As stated by the former UNESCO's Director-General Irina Bokova in The Hague during the Europe Lecture 2016, "The destruction of heritage is inseparable from the persecution of people. This is why we consider the protection of cultural heritage today as far more than a cultural issue. This has become a humanitarian imperative, and a security issue".

Fig. 4. Buddas of Bamiyan before and after the Taliban deliberate destruction as *idols*. (Source: Wikipedia)

The shift in the concept of built heritage from the ontological sphere of cultural expression to the international law domain of human rights re-casts the notion of its existence value. This latter, originally defined by Krutilla (1967) as *sentimental* value attributed to the *option* value of natural resources, encapsulates a much stronger and wider significance. As a result, the evaluation of the value of built heritage, whose conservation may indeed (and usually does) represent a relevant constrain in the planning practice, should be approached with a more cautious approach, such as the precautionary principle approach. This latter has been adopted by the UN General Assembly in 1982 and subsequently incorporated into various international conventions aimed at protecting the environment (EC, 2000). The principle was launched by the 1992 Rio Declaration, which states: "in order to protect the environment, the precautionary approach shall be widely applied by States according to their capability. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation". In consideration of the irretrievability of the decisions concerning the destruction of the built heritage assets as non-replaceable, taking in account the sustainability principle of intergenerational justice, it seems plausible that such a principle applies to the conservation of built heritage threatened by growing and rapid urbanization, by constraining the negotiability of decisions concerning its preservation.

Built heritage and spatial planning. Insights from a UK case study

Though some authors (Pendlebury, 2013; While, 2006) reposition heritage from being perceived as an obstruction to development to being understood as an agent of change, still the reality is far from this abstract concept. Rapid urbanization remains a major challenge for heritage conservation worldwide, and even in most advanced countries, with regard to the issue of heritage conservation and preservation. The second part of this paper elaborates on the principles presented in the previous conceptual framework, by instrumentally discussing an extant case study in the UK. The reasons for which this case has been chosen is that it is a paradigmatic case, representative of an average situation very common in urban context challenged by rapid growth. Moreover, the UK is a country with a very long tradition on conservation and with a solid policy and regulation framework for endorsing heritage preservation, thus flaws in achieving this goal cannot be ascribed to the lack of consolidated procedures. On the contrary, the case study demonstrates that the concept of heritage as negotiable matter within the spatial planning decision making process can irretrievably endanger local identity, cultural diversity and fulfillment of the principle of precaution with respect to the right of future generations to benefit from non-replaceable built heritage. The policy and regulatory framework for the case study is one of the most advanced legislation in terms of built heritage conservation, contextualized in a country with a long spatial planning and

community engagement tradition. The chosen case study is located in a growing urban area located in the North Western part of England, the Greater Manchester Area. This is a post-industrial context, which was severely challenged by the decline of the manufacturer industrial sector and experienced years of struggle and urban decay. However, a combination of economic policies, socio-economic interventions, urban regeneration strategies, allowed this area to regain its leading role in the region and to become attractive, up to the point that it is now challenged by the necessity to provide enough housing stock to a fast-pace growing population. In the Manchester area, a contradictory approach towards the heritage-led urban regeneration emerged during the initial stages of the recent urban regeneration process, well embedded in the debate surrounding the famous landmark Beetham Tower. This was the first high-rise building built in the formerly industrial area of Deansgate-Castelfield, today regenerated with the highest quality construction standards and revitalized thanks to the creation of new cultural and social hubs, such as the Home Theatre and Cinema Center. The architectural debate around the tower was lively, with one author suggesting that the building “torpedoed” the opportunity that Manchester was inscribed in the UNESCO World Heritage Cities list, at a time in which the city was shortlisted in the UK based on its industrial past (Punter, 2010). Today the Beetham Tower is surrounded by tens of high-rise towers, popping up at rapid pace into a skyline of cranes. Heritage conservation and preservation played indeed a relevant role in ensuring an excellent level of quality in the majority of the urban regeneration initiatives of the last 20 years both in the City of Manchester and in other cities of the recently established Greater Manchester Combined Authorities, including examples such as Ancoats, a recently regenerated area rich in stunning industrial architectures, the Northern Quarter, dotted by reused red-bricks historic buildings, and the numerous heritage mills rebirth to a new life as offices and apartment buildings along the extraordinary network of waterways and canals, and related engineering infrastructures. However, still in some case conservation of built heritage is not prioritized. A paradigmatic case is the Chapel Conservation area in Salford, where in the last few years two Victorian buildings have been demolished to leave room for the development of apartment buildings, indeed very high-quality design schemes, but ignoring the presence of two pieces of built heritage that would have increased identity and sense of belonging in the area. This case study is first contextualized within the UK policies on conservation, then discussed through archival data, planning documents and fieldwork conducted over a 4-years timeframe (2015-2019).

Contextualizing the case study: heritage conservation in the UK

Conservation of built heritage in the UK has a long tradition, dating back to the first Ancient Monuments Protection Act 1882, which granted conservation to selected archaeological monuments (Mynors 1999). Interest in monuments conservation stemmed from the Romanticism movement and in particular from the influence of William Morris, who in 1877 created the Society for the Protection of Ancient Buildings (SPAB) to advocate for the conservation of built heritage (Yu, 2008). The current UK regulatory framework on conservation of built heritage rests on three different levels of conservation: Scheduled Monuments; Listed Buildings; Conservation Areas. The definition of monument is stated by the Ancient Monuments & Archaeological areas Act 1979 as: “any building, structure or work, whether above or below the surface of the land, and any cave or excavation; any site comprising the remains of any such building, structure or work or of any cave or excavation; any site comprising, or comprising the remains of, any vehicle, vessel, aircraft or other movable structure or part thereof which neither constitutes nor forms part of any work which is a monument within paragraph (a) above”. The significance of monuments stems from their interest, which can be either archaeological (archaeological interest forms a primary source of evidence relating to the substance and evolution of places, plus the people and cultures that made them) or historic (interest in how the present can be connected through a place to past people, events and aspects of life. Monuments with historic interest provide a material record of the nation’s prehistory and history, whether by association or through illustration). The criteria for scheduling monuments refer to different features: period (monuments that characterise a category or period should be considered for preservation); rarity (monuments that are so scarce that all surviving examples that still retain some significance should be preserved); documentation/finds (existence of records of previous investigations); group value (association of the monument with related contemporary monuments and / or those of different periods); survival/condition; fragility/vulnerability; diversity; potential. Owners of a scheduled monuments need to apply for prior written permission from the Secretary of State for Digital, Culture, Media and Sport, under the procedure known as Scheduled Monument Consent or SMC (historicengland.org.uk).

Besides scheduled monuments, listed buildings are those, holding special architectural and historic interest. Listing brings a building under the consideration of the planning system, so that it can be protected for future generations (historicengland.org.uk). The Town and Country (Listed Buildings and Conservation Areas)

Planning Act 1990 includes among its roles being of “guidance of local planning authorities in the performance of their functions under this Act and the principal Act in relation to buildings of special architectural or historic interest”. The institution of the English Heritage (Historic Buildings and Monuments Commission) was owed to compile the list of the most historic interesting buildings, which following their inclusion within the list are defined as “listed” (Campbell, 2001). Listing is guided by the two main criteria: 1) value of the building, 2) period of construction. According to the Planning Policy Statement 15, the principles of inclusion in the List are: (1) Architectural interest: the lists are meant to include all buildings which are of importance to the nation for the interest of their architectural design, decoration and craftsmanship; important examples of particular building types and techniques (eg. buildings displaying technological innovation or virtuosity) and significant plan forms; (2) historic interest: this includes buildings which illustrate important aspects of the nation's social, economic, cultural or military history; (3) close historical associations with nationally important people or events; (4) group value, especially where buildings comprise an important architectural or historic unity; (5) fine example of planning (eg. squares, terraces or model villages). The Planning Policy Statement 15 also states principles to determine the historic interest of the buildings belonging to the categories presented above, considering worthy of listening “all buildings built before 1700 which survive in anything like their original condition are listed; and most buildings of about 1700 to 1840 are listed, though some selection is necessary. After about 1840, because of the greatly increased number of buildings erected and the much larger numbers that have survived, greater selection is necessary to identify the best examples of particular building types, and only buildings of definite quality and character are listed. For the same reasons, only selected buildings from the period after 1914 are normally listed. Buildings which are less than 30 years old are normally listed only if they are of outstanding quality and under threat. Buildings which are less than ten years old are not listed.” Listed buildings benefit from three different level of protection: Grade I (buildings of exceptional importance), Grade II* (particularly important buildings of more than special interest) and Grade II (buildings of special interest). Section 69 of the Town and Country (Listed Buildings and Conservation Areas) Planning Act 1990 defines Conservation areas as “areas of special architectural or historic interest the character or appearance of which it is desirable to preserve or enhance”. The definition of a Conservation area is instrumental to preserve a particular area or neighbourhood, while the listing procedure focuses only on individual buildings. Although some of the buildings in these selected areas may be listed, the importance of the area is stated by its special interest as a whole, which may include factors non related to the buildings themselves like the pattern of the streets and the skyline (Ross 1996). It is a duty of the local planning authority to identify which portions of its bailiwick are worth of protection due to their architectural and historical value (Campbell 2001). It should also establish the local standard to grant during the determination process as they are not prescribed. As the Planning Policy Statement 15 states the local authority in 4.4 paragraph “In deciding whether it is desirable to designate, an authority may take into account the resources likely to be required, not only for the administration of conservation area controls, but also for consultation with local residents and formulation of policies for a new area: without follow-up, designation is unlikely to be effective in itself.” The Planning Policy Statement 15 identifies also some other aspects to take into account for the designation of the areas such as: (1) the historic layout of property boundaries and thoroughfares; on a particular 'mix' of uses; on characteristic materials; (2) appropriate scaling and detailing of contemporary buildings; (3) the quality of advertisements, shop fronts, street furniture and hard and soft surfaces; on vistas along streets and between buildings; (4) the extent to which traffic intrudes and limits pedestrian use of spaces between buildings. The first conservation areas were designated in 1967 and there are now over 8,000 conservation areas in England (<https://historicengland.org.uk/listing/what-is-designation/local/conservation-areas/>). The United Kingdom Government set out its planning policies concerning the historic environment and designated sites for protection and conservation, termed as “heritage assets” in the National Planning Policy Framework (NPPF). The NPPF was published in 2012 and a new version of the NPPF was published in 2018. It defines a heritage asset as “A building, monument, site, place, area or landscape identified as having a degree of significance meriting consideration in planning decisions, because of its heritage interest. It includes designated heritage assets and assets identified by the local planning authority (including local listing)” (Ministry of Housing Communities and Local Government, 2018, p. 69). Conservation area designation introduces controls over the way owners can alter or develop their properties. These controls include control over demolition of unlisted buildings which requires a planning permission, control over works to trees and restriction on the types of development which can be carried out without the need for planning permission.

Case study discussion and findings

The Chapel Street corridor is a regeneration area in the city Salford, one of the cities included in the Greater Manchester Combined Authority area. It is located at walkable distance from to the city center of Manchester and is partly included in the Salford Central Masterplan, a 20-years regeneration initiative, one of the UK's largest development projects. The Salford Central Masterplan was designed with the goal to achieve “capacity to deliver £650million investment, create around 11,000 new jobs, 197,000sqm of commercial space, 24,000sqm of retail and leisure space, 849 new homes, 390 hotel rooms, new car parking, improved pedestrian and cyclist routes and new public open spaces” (www.salford.gov.uk). The economic impact of this initiative in the City of Salford is of outstanding relevance. During the industrial revolution the area underwent rapid change, the urban fabric was characterized by a tight grid of street and crowded houses. In the 1970s it began to decline and in the mid-1990s population was falling, many buildings were empty and left to decay and social issues arose (SCC 2008a). Due to these initial conditions, it is evident that the successful implementation of the regeneration scheme is particularly welcomed by the local communities and decision makers. The area is indeed rich in built heritage (Fig. 5).

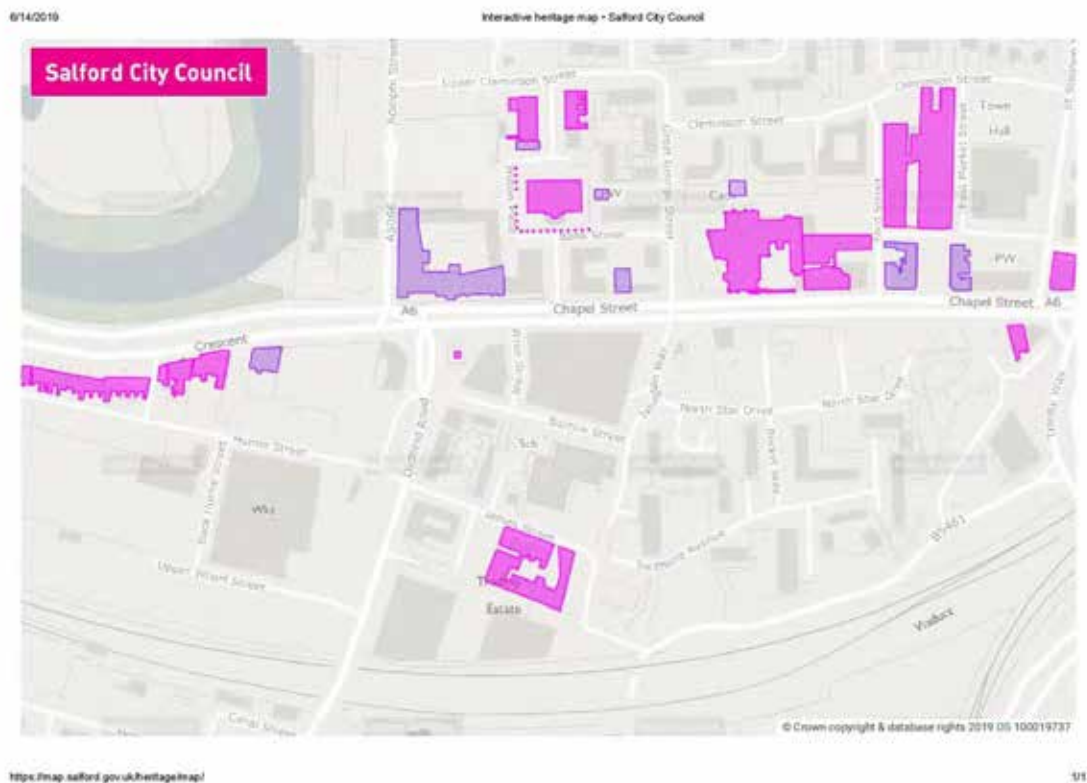

Fig. 5. Listed buildings in the Chapel Street study area (Source: map.salford.gov.uk)

It incorporates Grade II* buildings and conservation areas, including the Crescent and the Adelphi Buxley Square conservation areas (SCC, 2008a and SCC, 2008b). Overall, it is a key- corridor in the urban structure and should play an important role in the definition of the future identity of the local community. However, the approach to the conservation and preservation of built heritage in this area is controversial. The new projects within the Adelphi Buxley Square conservation area (SCC, 2007) have been implemented so far with a high level of consideration for the historical pattern of the urban fabric. For example, Timekeepers Square is a development of 36 townhouses that forms part of the English Cities Fund's (ECf) Salford Central regeneration scheme, which has been awarded multiple prizes including the RIBA North West Awards 2018 (<https://butfress.net/project/timekeepers-square/>). It perfectly fits into the urban surrounding, exploiting the potential of the visual connections between the Grade II* listed churches. On the other side of the Chapel Street corridor, the Crescent Conservation area has been recently challenged by the demolition of a Victorian building,

the Black Horse Hotel, which was recorded in the Crescent Conservation Area Appraisal (SCC, 2008b). The building was deemed not consistent with the regeneration plan by the developer, Fred Done's company, Property (Done) Ltd, consisting in the construction of about 400 rental flats in apartments of up to 22 storeys. The planning permission for the demolition of the building was passed by the Council despite serious concerns were raised by Historic England, the Victorian Society and the residents. According to Salford Star (7th April 2016), a representative of Fred Done's declared that "It wasn't feasible to keep the pub...we didn't want the pub...that was out of our hands". SalfordOnLine (7th April 2016), reported that the Victorian Society said the plans were "a poor scheme... setting a dangerous precedent for inappropriate development in conservation areas everywhere". The pub, built in 1875, was closed since 2000 and was in need of repair, but still remained on the council's own Local List of buildings of historical note. According to InsiderMedia (8th April 2016), a spokesman for the Victorian Society told Insider that the decision was "a disappointing one. As we pointed out in our letter of objection, the great harm that the scheme would cause to the conservation area and to listed buildings has not been justified in planning terms and it fails to comply with local and national policy. The opportunities provided by a site of this size means the loss of the locally listed Black Horse Hotel is entirely unnecessary. In almost every way this is a poor scheme and it sets a dangerous precedent for inappropriate development in conservation areas everywhere." Interestingly enough, difficulties in keeping the built heritage alive in the Chapel street corridor are arising in more recent times, while the initial reluctance to private investments in the area should have been partly overcome by the success of the scheme. In 2013, while the Chapel Street regeneration initiative was still in its infancy, the Old Bell Tower pub had survived risk of demolition, with "developers (who) had hoped to turn the landmark Bell Tower pub on Chapel Street into a residential development but instead fell into a dispute with Salford council" (Manchester Evenings, 2013). In 2016, the demolition of the Black Horse 1875 Victorian pub has been coupled by the Olde Nelson pub, originally built in 1805 and re-built in 1899, closed in 2002 and bulldozed following a "delegated decision" of the Salford City Council. This has happened despite of the fact that when the scheme was launched, the Planning Lead Member and Councilor Antrobus had declared that it was "essential that we preserve as many historic buildings as possible in the Chapel Street area" (Star, 16th June 2016). Antrobus further added that "Good planning means mixing the old with the new. It is essential that we preserve as many historic buildings as possible in the Chapel Street area", echoed by Salford MP Hazel Blears, who was photographed by the pub Salford MP Hazel Blears was photographed by the pub stating "Alongside the vital demolition work necessary to make the area safe, historic buildings and public spaces such as Ye Olde Nelson and Bexley Square will be revitalized and brought back into active use." Regrettably, two Victorian landmarks, one in the Crescent conservation area, another facing the Adelphi Buxley Square, have been reduced into dust to make room for new developments, which still hold the potential for adding value to the area thanks to the high quality of the design, though the decision of demolishing the two pieces of heritage has been made despite the opposition of local stakeholders with specific expertise in the Victorian heritage.

Conclusions

Despite of the growing importance that built heritage is gaining internationally, as essential and irreplaceable component of human-centred, inclusive and equitable development, still the implementation of such a strong paradigm is challenged by weak conservation policies at the local level. The implicit recognition of the significance of built environment within the human rights domain seems to be taken for granted in the formulation of the targets of Agenda 2030, which only focuses on the investments in the preservation of heritage but does not recognize the necessity of tracking the loss of built heritage, particularly under the pressure of real estate market and developers. There is an urgency for re-focusing the SDG11 Target 11.4, which should acknowledge both financial efforts on the conservation and preservation of heritage, but most importantly the willingness to retain such legacy for future generations. The first part of this paper widely discussed the contradictions created by the concept of heritage as social construct, whose significance should be assessed through a wide and participatory process, and the notion of heritage as legacy to be preserved for the benefit of future generations. It is suggested that the precaution principle should be applied in the decision-making process regarding built heritage, which is non-replaceable, thus decisions on it are irretrievable. Beside a recognition of the importance of the existence value of built heritage at international level, it would be extremely useful to avoid unnecessary destruction of built heritage under the pressure of real estate and developers, thus, there is an urgency for a reformulation of heritage values and related decision-making process within the local spatial planning agendas. The discussion of an extant case study demonstrated how even in one of the most advanced countries in terms of policies heritage conservation, in the practice this may not be the priority. It is suggested that heritage conservation should be re-casted within the spatial planning policies, by positioning it into a non-negotiable domain, thus allowing future generations to benefit from a non-replaceable asset.

Who is afraid of transition? Monitoring the impact of transformation on historical rural landscapes as indicator of communities' changing needs

Francesca Vigotti¹

¹*Politecnico di Milano, francesca.vigotti@polimi.it*

Abstract: Rural landscapes are a productive heritage. Consequently, these sites can be representative, more than others, of the quantitative and qualitative impact of macro-phenomena related to transition by monitoring transformations acting over them. This heritage is recently at the centre of a strong interest and debate. The challenges posed by a constantly transforming and stressed heritage led to an urgent need, emerged in particular in the last fifteen years, of an integrated approach that could cope with a complex background of issues, such as exogenous and endogenous pressures. However, at first instance, preservation approaches applied over historical rural landscapes focussed on a “crystallization” of these sites, although their intrinsic dynamism. Accordingly, some are the recent management tools dedicated specifically to this heritage, aimed to integrate preservation and planning policies (e.g. GIAHS, FAO). Their effectiveness is based on two main pillars, which differentiates them from previous approaches: first, the direct involvement of communities that have shaped, maintained and inhabited these sites over time, through an examination of newer needs derived from a recent opening to a globalized world; second, the definition of site-specific management plans able to change accordingly to the results of a participate monitoring over time, in the perspective of the definition of a win/win methodology including all the stakeholders involved (communities, agencies, institutions). The paper evidences the contraposition between the “fear” of an inevitable transformation and the potentialities they can generate as indicator of the transition effects on rural landscapes in time. Thus, the development of policies aimed to a dynamic preservation of this heritage must consider an accompanied and mutual support to transition between communities and professionals. To discuss this scenario, a comparison over the application of management and preservation approaches in two rural landscapes sites is given, to outline potentialities and critical aspects.

Keywords: Rural landscapes, integrated approaches, monitoring, dynamic conservation, communities

Introduction

The preservation of rural landscapes has gathered the attention of a growing number of scholars from different disciplines, since the early 2000s (Antrop, 2005; Antrop and Van Eetvelde, 2017).

The reason for this interest from a wide range of sectors lies also in the difficult determination of the concept of *landscape* itself which, as a “polysemous” (Gambi, 2000), “dense” (Varotto, 2018) or even “opaque” (Birks, 1998; Wynard Lion, 2007) term has needed to be adjectivized to delimit its meaning. The origins of the term *landscape* have had an influence over the definition of the concept *cultural landscape* nowadays: the fact that there is not a specific and unique definition might be a consequence of the ubiquitous use implied over the centuries of the word *landscape* in different languages (Meining, 1979, Rowntree, 1996; Taylor, 2009). From the restitution of the concept of *cultural landscape*, detailed by Carl O. Sauer in 1925¹, up to the most recent ones in the context of the preservation of the cultural heritage, which on the international level are identified in the definitions given by the World Heritage Center (United Nations Educational, Scientific and Cultural

¹ “The cultural landscape is fashioned from a natural landscape by a cultural group. Culture is the agent, the natural area is the medium, the cultural landscape is the result. Under the influence of a given culture, itself changing through time, the landscape undergoes development, passing through phases and probably reaching ultimately the end of its cycle of development”.

Organization - UNESCO, 1992)² and the European Landscape Convention (Council of Europe, 2000)³, substantial differences and implications have rose.

The limit to delineate the meaning of *cultural landscape* in a common and shared definition is reflected also as a first obstacle to overcome in approaching the safeguard and management of such heritage. Being complex and multidimensional, the main challenge is represented by a dualism of sense: on the one hand, a *forced* simplification and *impoverishment* of a multifaceted heritage, structured not only by many components, but also by the relationship intercurrent between them. On the other, the aforementioned presence of several and coexisting factors could lead to a picking approach, which investigates only partially the whole.

For long time, in fact, the anthropic and natural macro-components of landscape have been investigated as separate, taking little into account their crucial interconnections (Smith, 2006); or even, the presence of man and its action over nature has been considered as a critical aspect, “harming” landscape (Marsh, 1872). The origin of such *risk* has then been shifted towards the individuation of changes, transformations and development as main responsible of damage (Antrop, 2005).

Even though the interdependency between anthropic and natural factors is recognized nowadays (Bender, 2002; Lowenthal, 2005; Aplin, 2007), when it comes to deal with the safeguard of cultural landscape is necessary to underline how the theoretical and practical approaches experimented on the international level have led, until recent times, to the development of further critical aspects, part of which can be reconducted to the investigation methodologies themselves, and caused mainly by a scarce integration between the diverse systems and tools (Akagawa and Sirisrisak, 2008).

The framework of issues presented becomes even more evident when facing the preservation and management of rural landscape. This heritage, being productive, is representative more than others of the quantitative and qualitative impact of macro-phenomena related to transition and transformation, given its intrinsic dynamism.

As for cultural landscapes, of which they are part of, rural landscapes face two main criticalities in terms of safeguarding and monitoring approaches and tools. One is represented by the possibility to fall into a “crystallization” (Van der Valk, 2014)⁴ process of investigated sites, in which a “museumization”⁵ of inhabited places implies resultant issues in social, economic and ecologic terms. Second, and consequential, the chance to develop management policies that do not consider the sites as a palimpsest or a process still undergoing, but rather as a “result”. That being so, such dualism has been recognized in literature as a “dilemma” (Van der Valk, 2014), leading to a question: should policies focus on the possible future changes of a site, or rather just “preserving” the past?

The identification of rural landscape as heritage and its preservation. A matter of time

As the definition of the concept of *cultural landscape* as often lead not only to difficulties in developing effective safeguarding policies, but also to a simplification of such approaches, a similar course is occurring regarding the concept of historic or traditional rural landscape.

In this context also, in fact, there is not just one, shared and common definition.

² “(...) cultural landscapes represent the “combined works of nature and of man” designated in Article 1 of the Convention. They are illustrative of the evolution of human society and settlement over time, under the influence of the physical constraints and/or opportunities presented by their natural environment and of successive social, economic and cultural forces, both external and internal.” UNESCO: Cultural Landscapes, Date of access 1/11/18 <http://whc.unesco.org/en/culturallandscape/>,

³ “Landscape” means an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors;” European Landscape Convention, Article 1 “Definitions”, section “a”, Council of Europe (2000)

⁴ Van der Valk defines “immobilization” with the concept of “landscape mummification”

⁵ The phenomenon of “museumization” is expressed as: “(...) presenting and interpreting cultural groups and their representative tangible and intangible heritage. (...) It has produced stereotypes derived from the past constructions of the Other, such as (...) the freezing of indigenous peoples and minorities in the old anthropological time frames. (...) has been a concern in heritage tourism and sustainable development.” Galla A. and Paulo D., 2016, Museumization. In: Encyclopedia of Tourism, edited by Jafari J., Xiao H. (Cham: Springer)

The main critical aspect, when speaking of which sites can be defined as historic rural landscapes, is not about an *adjectivisation* of the world landscape itself -as occurred in the case of cultural landscape - so as to add a peculiarity to the word and better define this complex heritage; rather, the main issue in defining historic rural landscapes lies in *time*.

In literature, rural landscape is frequently addressed as *traditional* or *historic* (Antrop, 1997, 2005; Torreggiani *et al.*, 2014; Barbera *et al.*, 2014; Brogiolo and Colecchia 2017).

A rural landscape is assigned to the first or second definition by delimiting in which span of time a site has constituted and consolidated its peculiar elements. Two are the issues identified in reviewing the definitions: first, *traditional* and *historic* concepts sometimes overlap (Ludwiczak, 2012), while in certain cases the choice between the two classifications leads to a different identification of sites.

Therefore, a historic landscape cannot be claimed as *traditional* just because it was not strongly stressed by the impact of transformations occurred after the industrial revolution, such as mechanization of agricultural practices or changes in the species cultivated: in fact, there are no rural landscapes which were not affected (even in minimum part) by such processes of change.

The process might be represented both as a sudden event or as a slow modification: the crucial point concerning the determination of being a site historic or not therefore cannot be associate only to changes developed gradually in time, but instead all stages must be considered in the analysis.

As a matter of fact, transformation in rural landscape constantly occur. Therefore, the issue is represented by the delimitation of a time span in which a rural landscape, to be defined as historic or traditional needs to be identified within. Thus, defining a rural landscape within one of the two concepts basing on a belonging era might result in a contradiction, being rural landscapes a process still on going and in constant modification, a palimpsest of individual and collective stories and narratives.

Thus, by choosing a certain segment of time as more significant to be considered or preserved, it comes a misinterpretation in investigation and research: a historic rural landscape must be analyzed as a continuum that includes all the phases of a still lasting process. This reflection is well explained by Renes (2015): in the challenging tentative to define the concept of historic rural landscapes and, overall, what should be considered within this definition, the result often led to a forced simplification of this heritage.

The concept of heritage, in a broader sense, is itself considered a process (Harvey, 2001): the same can be assumed when investigating historic and traditional rural landscape definitions; as landscape is “time materialized” (Bender, 2002), also the meanings associated with it as heritage must not stand still, but rather developing accordingly to changes in context. The IFLA-ICOMOS (International Federation of Landscape Architects – International Council on Monuments and Sites) *Principles concerning rural landscapes as heritage*, as the most recent definition, synthetize effectively the urgency to overcome the question over time and transformations: “*Rural landscapes as heritage are expressions of social structures and functional organizations, realizing, using and transforming them, in the past and in the present. (...) All rural areas can be read as heritage (...) traditional and recently transformed by modernization activities: heritage can be present in different types and degrees and related to many historic periods, as a palimpsest.*” (2017).

That being so, the “dilemma” cited above between preservation of the past or management of change regards the dimension of *time* in a broader sense. Being rural landscapes a *palimpsest* it is not possible to define, or better prefer, which layer deserves more than others to be preserved: and even is critical to delimitate time spans in which a rural landscape might be considered as historical. The choice to preserve only a portion of a landscape, given the fact that it is considered more “relevant” than the whole that composes its context, poses an inevitable contradiction even with the principles stated in the European Landscape Convention.

Preservation policies must therefore include all the transformations and the intertwines that occurred in the past and are on-going today, since it is this intricate network that reinstitutes the complex scenario that has to be safeguarded.

Dealing with change and communities needs in rural landscapes: a review of management and preservation methodologies applied at the international level

At the international level, there are different methodologies that have developed since the eighties of the twentieth century for the preservation and management of rural landscapes, diverse in terms of research realm and specific objectives. The ecological approach, as an example, implemented at first the Integrated Conservation and Development Projects (active for just over a decade until the early 2000s) and subsequently Community based conservation programs (Little, 1994; Berkes, 2003; Campbell and Vainio-Mattila, 2003; Folke *et al.*, 2003; Garnett *et al.*, 2009).

Both the methodologies are centered on the communities that live and manage the rural landscape; the tools express the will of integrate development and conservation policies of the rural sites by involving the population. Another contribution is given by the contractual tools of management and protection of rural landscapes, as Payments for Environmental Services (Pagiola, 2007; Leimona *et al.*, 2008; Wunder, 2005, 2015).

In the field of heritage preservation on a supra-national level, the World Heritage Center (UNESCO) counted (as of 2018) 29 sites that can be identified as rural landscapes listed as World Heritage (UNESCO, 2018). The process of safeguard developed by the World Heritage Center includes criteria to be respected both in the phases of nomination as World Heritage site and in the subsequent periodic monitoring; furthermore, from 2005 management plans are compulsory for nominated sites.

Besides these efforts, today these procedures are still applied on a *recommendation* level, which is independent of the category of heritage examined: moreover, management plans rarely provide specific indications on the criteria for monitoring the changes taking place on the sites examined. Although, during the thirtieth session of the World Heritage Convention (Vilnius, 2006), the need to create a set of indicators that could render the criteria indicated by operational guidelines less *discursive*, emphasizing how “*setting precise but realistic and measurable results and indicators is essential for effective performance appraisal and monitoring*” (UNESCO, 2006) and that a first draft of these indicators was carried out by ICOMOS UK (2006), the development of the criteria was not completed. To date, a set of indicators (although partial) can be found in the management plan compiled for the Stonehenge site in 2009 (Young *et al.*, 2009).

This inclination to the difficult dialogue between site management policies and those more closely related to the safeguard of rural landscapes has only recently been partially overcome, through the identification of operational and analytical methods that comprise a broader spectrum of disciplines and related skills (e.g. preservation of heritage, geography, economy, ecology, archaeology) in a holistic and inclusive perspective of management.

An example is represented by the FAO Globally Important Agricultural Heritage Systems (GIAHS) program, active since 2005. GIAHS foster a dynamic approach aimed specifically to the protection and development of historic rural landscapes, acting on a global level; the program directly involves the population, by using also contractual tools. The community is supported by experts from different sectors in the process: unlike other analyzed methodologies, the GIAHS are articulated on the community that lives and that has created the rural landscape subjected to the program.

In the given context, management plans as GIAHS can represent a significative step forward in terms of definition of policies. Firstly, the system overcomes the concept of historical rural landscapes as an object focusing rather on this heritage as a process: the core of this shift is given by the role of the community in all the steps related to the inclusion of a site in the program, from its individuation to the management after the nomination.

The milestone is represented by a premise: a site should be included in the program only if the nomination process is shared by the community that inhabits it. Such standpoint has one main implication: as the policies are community-centered, the management plan can be adapted accordingly to the developing needs of the inhabitants (Altieri and Koohafkan, 2003; Howard *et al.*, 2008; Boerma and Koohafkan, 2010).

Concerning the presented methodologies, although progress has been made in recent years in the process between the theoretical and practical application of policies, some critical aspects persist in

the effectiveness of evaluation of the different approaches over time. The current methodologies for the protection and conservation of historic rural landscapes, in particular those relating to management plans, although present shareable objectives, appear still unclear in monitoring implemented actions (Alumae *et al.* 2002; Agnoletti, 2014; Palang and Fry, 2015). The risk is that of not being able to monitor the actual implementation of the proposed policies in a timely and effective manner.

Indicators for monitoring transformations in rural landscapes: an overview

Although in the literature well-structured proposals regarding the evaluation of the integrity of rural landscapes have already been advanced, it was found, however, that there is still a relative lack of monitoring indicators over both risk management and the effectiveness of the policies applied.

In order to be able to assess the impacts of transformations and, consequently, indicate and structure which mitigation policies of the phenomena encountered may represent an effective response, an in-depth investigation must be carried out into the sources of statistical data and the information measuring the indicators. In fact, incomplete or unreliable sources can cause an inaccurate assessment of the impact of the phenomenon: the prepared counteraction actions, therefore, can be underestimated with respect to the criticality found.

The usefulness of the indicators is reflected in the restitution of a synthetic meaning: they are developed on the one hand to reduce the number of measurements necessary for returning an "exact state of the art", and on the other to improve the communication of results measurements to end users.

At an international level, the Organization for Economic Cooperation and Development (OECD) developed a set of indicators for assessing and monitoring sustainable development, presented in a first report published following the Rio Conference in 1992. Ten years after the first report, having collected and analyzed the critical aspects in the application of the indicators provided in the first phase to assess rural landscapes, OECD developed a document that gives a framework of the evaluations expressed in different countries (NIJOS/OECD, 2002). Although there are some general considerations important for the implementation of assessment criteria (e.g. quantifiable indicators), the contribution does not show the will to address the indicators towards an analysis on the impact of the phenomena that act on the rural landscape, but rather the assessment is limited to its characteristics.

In the same years, in the European context, following the ratification of the European Landscape Convention (2000) the theme of monitoring the changes and risks (endogenous and exogenous) to which the rural cultural landscape is subjected becomes central.

This has therefore led to the development of new researches: in the Italian context, the first important study is due to the research group of Vallega (2008). By interpreting the text of the ELC and the given definition of *landscape*, the research outlines indicators referred both to objective characteristics of landscape (e.g. natural and socio-economic processes) and to others related to perception aspects. In the design of the indicators, therefore, four reference contexts are taken into consideration: ecological, socio-economic, cultural and institutional.

Concerning the monitoring over UNESCO World Heritage listings, the Università di Torino investigated over nominated rural landscapes sites (2013-2015). In the research, reference is made to the indicators for the evaluation of sites, structured in four categories: economic, historical, socio-economic and managerial (Gullino *et al.*, 2013). The focus of the investigation of the considered sites lies in evaluation of *integrity* concept as defined by the World Heritage Center. Thus, changes are not quantified through units of measurement. The evaluation of the management plans applied to the examined sites is also limited to a comparison made in a descriptive way of the most recurrent phenomena, thus not quantifying the impact of the identified phenomena (Gullino *et al.*, 2015). In the same years the investigation of the Universities of Palermo, Tuscia and Molise led to the definition of a set of specific indicators for the analysis of the transformations of the traditional agricultural landscape (Paesaggio Agrario Tradizionale - PAT). The main difference compared to what was observed in the abovementioned investigation lies in the articulation of indicators that are mostly quantitative and measurable, associated with a specific unit of measurement. By subdividing the

families of indicators into frames of reference for the analysis of the environmental, productive and social and settlement structure, the model consists in analytical system providing a global assessment of the identified issues (Marino and Cavallo, 2014; Barbera *et al.*, 2014). The Italian Ministero delle Politiche Agricole Alimentari, Forestali e del Turismo developed the National Register of Historic Rural Landscapes in the context of the "National Observatory of Rural Landscape, Agricultural Practices and Knowledge", in which a site can be registered only if it corresponds to the parameters of "significance, integrity and vulnerability" of historical rural landscapes, widening the UNESCO criteria. The tool for checking the transformations of historic rural sites in this case is present in the VALutazione Storico Ambientale methodology (VASA): a diachronic reading of permanence derived from data relating to soil consumption (Ministero delle Politiche Agricole Alimentari, Forestali e del Turismo).

Every action has a reaction. A review of changes, transformations and management plans in two rural landscape sites

The sites compared in this section have been selected not only for the similarities they have in the peculiar characteristics of which they are composed, albeit with differences, but also for the consequences of the choices that management plans, practices and regulations at national and supra-national have involved in safeguarding rural landscapes.

Ifugao terraces, in the Philippines, faced issues in the application of management plans and regulation, both developed by the national authorities and the UNESCO. On the national level, starting from the 70s in the context of the so-called Green Revolution, the government adopted actions in order to make the land more competitive on the international market. The main change was the introduction of new varieties of rice, developed to have a higher productivity rate than the traditional ones and, at the same time, to reduce cultivation times. The irrigation system and crops in Ifugao terraces have been managed for centuries on a democratic basis; the traditional system has been built and adapted over time to cope and avoid possible conflicts that could have arisen from the needs of the individual towards the community. This management, which was in charge to the community, went through substantial changes in the last thirty years. Based on a government decision, and subsequent to the effects of Green Revolution, since 80s the National Irrigation Agency (NIA) has taken the place of the collective management of the water resource. The main reform regarded the maintenance of irrigation canals by using concrete, considered more resistant for purpose. In monitoring the process of change, Acabado (2015) reports how the intervention on the canals was already out of order in a short time: concrete structures damaged rapidly, causing interruption in the water system. Analyzing the literature (Hayami, *et al.*, 2000), it is also reported how NIA had already entered into financial and technical difficulties from the 1980s, lacking to maintain the international competitive standards that follow the pressure of Green Revolution.

But Ifugao rice terraces do represent a milestone also in the UNESCO World Heritage list, being the first *cultural landscape* nominated in 1995 (UNESCO, 1996). At that time, the nomination process did not require a management plan for the site to be submitted by the State member (management plans will become compulsory in 2005). If, on the one hand, the listing of the site as World Heritage had the purpose to preserve the Ifugao terraces from the changes imposed by the Green Revolution, which were harming traditional cultivation and the structure of the *Cordilleras*, on the other the nomination acted as trigger for sudden changes. International and domestic tourism rose at an impressive rate; in just three years from the listing, the government asked for assistance so as to prevent changes in land-use, abandonment of cultivations and damages to the irrigation system (UNESCO, 1998). In short time, terraces were inscribed in the *In Danger* list (UNESCO, 2001). After eleven years of efforts and by including the community in the decision process, also by entering in the GIAHS program as pilot site in 2005 (and being nominated in 2011) the site was removed from the *In danger* status (UNESCO, 2012).

A similar path is traced in the *subaks* system of Bali, Indonesia. The cultivation practices of the site are strongly intertwined with traditional ecologic knowledge and religious aspects: the culture system revolves around the rituals based on the philosophical principle of the *Tri Hita Karana*. The whole society is organized in the *subak*: community of farmers who manage and share land and resources,

cultivating rice with traditional techniques. The rituals related to water and the temples voted to it are the foundation of the *subak* itself. It is estimated that there are 1200 *subaks* on the island, and that the water system is managed by about 4000 farmers (Salamanca *et al.*, 2015).

This complex system, as happened in the Ifugao rice terraces, encounter a first crisis in the context of the Green Revolution. A variety of non-native rice was introduced: growing at particularly high rates, it allowed to harvest up to six times more cereal in two years than to the use of consolidated cultivation techniques. Issues rose rapidly: if on the one hand there were benefits, at least from the economic and productive performance, on the other farmers faced for the first-time scarcity of water resources. A second change occurs in the 1980s, when the Indonesian government decides and implements a plan of management of the irrigation network called the Bali Irrigation Project: this program should have improved the canals system. Again, the imposition of new rules and the lack of dialogue between government and the population has led in a short time to the suspension of the program, given that the community showed strong disagreement towards newly introduced practices, which considered water-related rituals partially (Lorenzen and Lorenzen 2005). The position taken by the community derives from the precise rules regarding the management of waters and the rituals associated with them.

Concerning the listing of the site as World Heritage (2012) the path that led to the nomination of the *subaks* and the subsequent management of the site presented some critical aspects. As noted by the report edited by the Stockholm Environment Institute (SEI) (Salamanca *et al.*, 2015), the management plan and the regulations put in place following the appointment of *subaks* in the list had issues in conduct the site through proper management. A cause of the partial failure of the implemented policies is attributable to the lack of a specific approach to the site itself. The development of a management program that, at least initially, is designed to be potentially applicable to very different situations has posed a series of problems deriving mainly from the top-down nature of the method itself.

A further factor that has placed critical points in the relationship between the government and local communities has been the decision to set a “pay per access” to part of the site, setting a ticket to access the World Heritage area. Although this decision could be a possible source of income for the families belonging to the *subak* object of the intervention, the government pronouncement to entrust the management of the tourist infrastructures to an external company has raised strong controversies from the community, felt excluded and deprived of decision-making power. Furthermore, the decision to provide tourist services with only a part of the UNESCO site led to protests by neighboring *subaks*, who fear a substantial economic loss as a result of this fact.

The top-down approach imposed by the government and the agency led to disagreements concerning mainly the exclusion not only of the communities themselves, but above all of their representatives from the assembly. Finally, the inhabitants complained about the absence of guidelines that could effectively explain the correct administration of the site.

In both presented cases, is evident how the application of top-down policies has led to inevitable conflicts and exposure of the inhabitants and landscape to new types of pressure; furthermore, it is shown how transition from a condition to another frequently leads to modifications of which real consequences can be not immediately noticed.

In the context of rural landscapes such transformations can be represented, to cite some examples, by the substitution of traditional cultivations with newer species, or by the introduction of different irrigation systems. Such interventions might be derived from authorities’ decisions, maybe not including the community in structuring policies, even if the population will be like in charge of practically accomplish over the site what was planned.

For example, the appointment of the rice terraces of Bali has attracted international attention to them, having as consequently an unprecedented series of threats (e.g. pressure tourist, economic rivalry linked to land holdings, loss of biodiversity). At the local level, the lack of an inclusive management plan has given site residents a secondary role, causing the progressive loss of the main agent of landscape transformation.

The introduction of non-native species in the crop cycle can lead to decidedly impacting effects on the sites themselves. Since this heritage is so strongly founded on the interweaving of ritual, religious and traditional practices with those that regulate the cultivation of local species, with the timing and the methods that these have followed for centuries, even a minimum change is sufficient to create an unbalance.

If the policies of protection of the site, recognized as heritage, moved in the direction of the conservation and prevention of possible interference due also to the introduction of "new" elements in the landscape, on the other hand the programs of governmental origin with regard to in the agricultural field do not question themselves with the same problems, replacing the native species with modern varieties of culture.

At first, the impact of changes might result in a positive impact to all the stakeholders involved: if the decision of install a more fruitful cultivation could on the one hand increase the production of a sector and result in a more immediate earning for farmers, on the other if not regulated it can lead to the exploitation of fields, causing loss of fertile land and biodiversity over time.

As shown, both the sites were at the center of "power relations": the local economy has found to confront itself with a market on a larger scale, even without the necessary preparation in a rather sudden manner, in which new scenarios for agriculture and, at the same time, new economic sectors that allowed a greater gain in less time than those of traditional rural activity were outlined for the community.

In situations like the ones just described we are witnessing a paradox: an action considered innovative and that aims to be an improvement, but applied without having a deep knowledge of the territory and its characteristics, has an opposite impact compared to the initial intentions.

Some remarks. Who is really afraid of transition?

Given the complex background of investigation methodologies, researches, tools dedicated to the management and safeguard of rural landscape, a main critical aspect emerges. As Renes states, in an effective synthesis "*Landscape preservation means management of change*" (2015): a reflection that implies the consideration of transformations and changes more than a "matter of fact" in safeguarding rural landscapes, but as the continuous action that relates all the components of this heritage.

As shown, policies that tend to an "immobilization" and that do not cope with the inevitable changes in site represent a potential risk themselves. The fear of transition that seemed to have prevented policies to act accordingly to transformations must be overcome in a broader sense, so as to develop preservation and management methodologies that are passible of modification in the whole process that leads to the safeguard of a site, from the policies design to application and monitoring.

Transformations on rural landscapes do not necessarily have, as a consequence, the complete losing of those characteristics and structural elements that represent a site and make it peculiar. Changes imply modifications over a site, sometimes necessary to cope with the needs of its inhabitants, posing new challenges: that being so, policies of management and safeguard must be developed accordingly, through a critical contextualization of the endogenous and exogenous phenomena (e.g. social, economic etc.) that brings transformation over this heritage.

As presented in the two sites analyzed, transition is critical when is managed as an obstacle to preservation, regarding changes only as a harm, rather than a driven of opportunities, and leading to actions that crystallize sites. But rural landscapes are a living heritage: the dilemma then goes beyond the one regarding dynamism and stillness in developing preservation and management policies: attention must be given to the actors that will play a role in this framework, and specifically to the position that each stakeholder will represent.

Paradoxically, rapid changes and their consequences over the social and environmental system constituting historical rural landscapes might act as trigger for the development of management and conservation policies: this could happen when awareness of the intertwines between transition effects and the evolution in the needs of a community rise.

For these reasons it is not possible to read all transformation that constitute rural landscapes as singular events, but rather there is the need of reflecting over the possible multi-level results of decisions. Furthermore, is fundamental that the preservation of rural landscape comprise the whole site, and not only the parts considered “significant” due to the fact that transformations have act less over them.

The dimension of time, then, closes the circle: overcome the dilemma means to consider that each element, relationship and system is destined to transformation, and a successful management plan should adapt accordingly to this dynamism.

In the given context, management plans must overcome stillness when defining policies. Being rural landscape a heritage-process, and in continuous change, it is therefore necessary that methodologies of investigation and programs applied to sites are structured as adaptable, through a management that includes transformations as “backbone” to develop policies.

Reconstructing public history through European settler and Indigenous heritage and landscape

Ryan Walker

Department of Geography and Planning, University of Saskatchewan, Canada, ryan.walker@usask.ca

Abstract: City planners and civic officials are delving into the implementation of actions for truth and reconciliation following the 2015 report of the Truth and Reconciliation Commission of Canada. Dolores Hayden reminds us that when read as stories of our city-region's public memory, the landscape, with built, natural, cultural, and spiritual dimensions, can tie our individual identities into something larger, a community that has a powerful sense of place. This paper draws on archival research and site visits to understand the built, natural, and cultural heritage on an 11 hectare site in the city of Saskatoon, Canada, that was part of the Plains First Nations territory for thousands of years, followed by the Métis nation, European settler homesteads, later as a leisure space for urbanites in a growing city, then as a retreat for Catholic religious orders of Sisters. For the past 12 years, it has remained closed to the public, fenced off and awaiting re-imagination and re-use by a local conservation organization, the Meewasin Valley Authority. This paper concludes with recommendations on how to use the thousands of years, eras, and worldviews behind the heritage of the site to create a powerful place for urban truth and reconciliation.

Keywords: heritage; city-region; settler; Indigenous

Introduction

The Peggy McKercher Conservation Area (PMCA) is an 11 hectare site owned by the Meewasin Valley Authority (MVA) outside of the built-up area of the city of Saskatoon, but inside its northeast municipal boundary. The PMCA is situated atop the edge of the South Saskatchewan River valley, with roughly 1 km of beautiful river overlooks, at the end of what is referred to as the Small Swale, a native temperate grassland ecosystem intact for over 10,000 years with high biodiversity. Saskatoon's current population is roughly 250,000 people, with large Indigenous (First Nations and Métis), European-settler descent, and diverse international newcomer populations. It is the largest city in the Province of Saskatchewan at the centre of the Canadian Prairies. The MVA is a conservation organization created in 1979 with three partner organizations: the City of Saskatoon, Province of Saskatchewan, and University of Saskatchewan. Its mandate centres on conservation, education, and development for the purposes of protecting the river valley's natural and cultural heritage and enabling public access to it.

The history of European settler society in Canada has been characterized by colonial violence toward Indigenous peoples. A significant part of this process was carried out through the federal government-funded residential school system run by Roman Catholic, Anglican, Presbyterian, and United churches, where Indigenous children were taken away from their families and home communities and taught – often violently – to reject their cultures and communities in favour of aggressive assimilation into a western settler and Christian society. Residential schools began operating in the late 1800s in Canada, and the last one closed in 1996.

Apologies have been issued by the Prime Minister and many church leaders in Canada. The effects of residential schools are multi-generational and reparations for this darkest chapter of settler colonialism will similarly take generations of work. As a way to acknowledge the true actions and impacts linked to residential schools and colonialism, and to try and move Canadian society, and the Indigenous nations within, in a direction of healing together, the Truth and Reconciliation Commission of Canada (TRC) was created. For several years it gathered evidence and facilitated truth-telling and reconciliatory dialogue in communities across the country. In 2015 the TRC released its final report. As peoples, governments, and religious organizations across Canada take steps to implement change according to the TRC guiding principles and calls to action, in view of the truth told by Indigenous residential school survivors, it is critical to create opportunities for constructive engagement between Indigenous and non-Indigenous peoples at the local scale. The local scale is created by unique place histories, relationships, and landscapes that have been witness to and constitutive of public memory, and it is a powerful scale at which to act in order to strengthen the bonds of society.

Using place, heritage, and landscape as a conceptual foundation, this paper examines how Indigenous and European-settler history are layered with the natural and settlement processes at what is now the PMCA site. This is done by appealing to literature and archival evidence relating to four historic phases of use on the site, supplemented by site visits. The archives at the Roman Catholic Diocese of Saskatoon were critical for this research, as were sources held by the MVA, the Local History Room at Saskatoon Public Library, and the Shortt Collection at the University of Saskatchewan Library. This paper argues that the PMCA is a powerful prospective site for heritage conservation, inter-cultural dialogue, and addressing some of Saskatoon's societal challenges relating to co-existence, natural, and cultural conservation. I argue that the strong shared place attachment across peoples and eras, and the environment itself, make this site invaluable for deploying heritage conservation, dialogue, and mutual learning, in the service of active reconciliation.

Conceptualizing place, heritage, and landscape as public memory

The interrelationships between physical setting (materiality, appearance), activities (programming, functions) and meanings (symbols, memories) – past, present and future-oriented – create a sense of place (Relph, 1976). Yi-Fu Tuan (1974) uses the concept of *topophilia* as a way to describe the qualities such as meanings, attachments, or memories that people develop for particular places. Place has a texture created by changing human-environment interactions and social relations over time, giving it depth and complexity beyond what is perceived on the surface (Adams *et al.*, 2001). At the time of European settlement in Canada, across Indigenous territories, newcomers did not typically recognise pre-existing Indigenous places on traditional lands and seek to humbly co-exist alongside them. Instead the colonial processes of planning, private and market-based land title, and homesteading policy and land parceling were directed at replacing Indigenous places with settler colonial landscapes (Nejad and Walker, 2018).

Tuan (2001) uses the terms “hearth” and “cosmos” as a metaphor for how places speak to our dual nature as humans, made up of what our body needs and desires, and what our minds long for and pursue. The hearth is local, warm, cozy, familiar, nurturing. The cosmos is large, abstract, and drives the excitement of exploring the unknown in the world beyond. Having places in our environment that satisfy our need for hearth and evoke the mystery of the cosmos is important for achieving a high quality of life and contentment. The hearth for one person or community might be the cosmos for another, and in this dynamic tension create a richer and deeper sense of place that is multi-layered, textured, where different specific affinities to the layers of place history and characteristics exist for different peoples, but where sufficient common ground drives joint stewardship. Learning how different people(s) experience the same place builds empathy and can strengthen social bonds.

Non-representational theories in landscape and heritage studies have brought new emphasis to the sensual human experiences of smell, sound, feeling, and emotional dimensions of place (Harvey, 2015). When the temporal past and future is kept prominent among affective dimensions which enliven the present, the dialogical

process of heritage conservation among public and experts, and among different cultures and worldviews, has great capacity for social and environmental impact. Dolores Hayden (1995) reminds us that when read as the stories of our city-region's public memory, the landscape, with built, natural, cultural, and spiritual dimensions, can tie our individual identities into something larger, a community that has a powerful sense of place, a shared hearth in the larger cosmos. Our urban and regional landscapes frame the lives of many generations and outlast many lifetimes. Their protection needs to be driven by a strong sense of guardianship, obligation, and reverence.

Rodney Harrison (2013) prioritizes materiality, connectivity, and dialogue in his approach to identifying, understanding, and conserving heritage sites and landscapes, emphasizing the bringing together of people(s) and creating space for different perspectives and worldviews. The heritage landscape and perception of oneself in it changes with the depth of temporality and cultural plurality that becomes subject to dialogue (Harvey, 2015). The nature versus culture, and monumental versus intangible dualisms in heritage discourse limit our ability to understand the actual lived experience in heritage landscapes, and the impact its conservation can have in critical societal change, addressing issues like cultural and environmental sustainability, economic inequality, social cohesion, urban futures, among others (Harrison, 2013; Winter, 2013). Indigenous ontologies have advanced our understanding of the kinship ties between human and non-human animals, plants, and the assemblage of living and non-living elements that make up our environment, expanding the notion of 'social relations' to include these human to non-human bonds (Harrison, 2013; Walker *et al.*, 2013). Trying then to draw lines between cultural, natural, monumental and intangible heritage seems deficient given our evolving understanding of the 'connectivity ontology' that infuses heritage with meaning in the midst of societal challenges like environmental degradation, species extinction, climate change, and fractured relationships between peoples (Harrison, 2013).

Using heritage to promote truth, justice, reconciliation and healing from conflicts emanating from the past, and potent in the present, has been a transformative tool in Northern Ireland (Crooke, 2010). Key to critical and transformative heritage is centring the 'sociality' of creating community, rather than trapping it in historic caricatures (Waterton and Smith, 2010). The dialogical aspect of heritage must be free to create or re-configure the contours of community through appeals to shared causes and interests in the present, and mutual understanding of one another's lived experiences. The dialogical process must be directed at producing a sense of place that is fluid over time, that acknowledges difference as much as unity, conflict as well as cohesion, and affinity in addition to separation among people(s). It must specifically avoid the tempting trap of seeking to patch over complex pasts (Burkett, 2001; Waterton and Smith, 2010).

First Nation and Métis territory – Treaty 6 – Temperance Colonization Society

The Saskatoon region has been inhabited by many different Northern Plains First Nations for thousands of years. The Cree and Assiniboine, followed by the Métis and Dakota, lived and hunted along the South Saskatchewan River prior to settlers of European descent arriving to establish communities in the Saskatoon region during the 1880s (Waiser, 2016). Just across the river from PMCA is a roughly 2.5 km² site called the Opimihaw Creek Valley, located for the past 30-40 years within Wanuskewin Heritage Park. As University of Saskatchewan archaeologist Ernest Walker (2016), one of the principal leaders who sought protection for the site points out, the Opimihaw Creek Valley was a gathering place in continuous use by successions of different First Nations for bison hunting, medicine gathering, habitation, sacred cultural and spiritual purposes as far back as 6,000 years ago (Walker, 2016). "Perhaps most extraordinary is that every cultural group that existed across the Northern Plains throughout the milleniums spent time at Opimihaw Creek" (Walker, 2016, no page). In 1876 Treaty Six was negotiated between the British Crown and Cree, Assiniboine, and other First Nations, setting terms for future co-existence in the Saskatoon region and beyond. First Nation use of the Opimihaw Creek site was overtaken by settler homestead parceling and private property rights, until reclaimed as Wanuskewin Heritage Park less than a century later, through efforts by the MVA and a number of First Nation

and non-Indigenous partners. In 2017 Wanuskewin Heritage Park was added to Canada's tentative list for designation by UNESCO as a World Heritage Site.

The Saskatoon region is a significant part of the Métis nation homeland, emanating west from the nation's heart at the Red River settlement (present-day Winnipeg). Part of this homeland includes the Round Prairie Métis settlement (La Prairie Ronde), which was one of the largest in the territory, roughly 30-40 km south of present-day Saskatoon, and located next to, with close community ties to, the Whitecap Dakota First Nation's reserve at Moose Woods. Round Prairie got its start in the 1850s when about 30 bison-hunting Métis families travelled there seasonally from the Red River settlement, and then in the spring of 1870 settled there permanently (Schilling, 1983; Troupe, 2009). Another important Métis settlement is Batoche, perhaps the most significant single community in the Métis nation's homeland regionally and provincially, and at the centre of the Northwest Resistance in 1885 led by Louis Riel and Gabriel Dumont. It is roughly 90 km to the north of Saskatoon. The historic Moose Woods – Batoche Trail, connecting the Round Prairie and Batoche settlements, was an important route connecting Métis and First Nations communities, and passed through the site that would become Saskatoon. Kinship ties between the Round Prairie and Batoche Métis communities led to them fighting alongside one another during the Northwest Resistance against the Canadian government forces sent to enforce the imposition of Canadian land title over the pre-existing Métis rights in the territory (Troupe, 2009).

Across from the Opimihaw Creek Valley, on the east side of the South Saskatchewan River, were grasslands, wetlands, and forest where First Nations and Métis peoples hunted, among other things. Here the Moose Woods – Batoche Trail passed through the quarter section of land immediately east of the PMCA site. There is a significant water spring on the PMCA site, which appears to be joined to the main trail by a secondary trail (Enns-Kavanagh, 2008). That water spring, referred to again in subsequent sections of this paper, was a likely spot for travellers to stop along the Trail, rest, and water their animals (Enns-Kavanagh, 2008).

In 1881 the Temperance Colonization Society formed in Ontario with a view to creating a prairie agricultural community following the principles of the temperance movement – believing alcohol was largely to blame for social and moral decline – led by a Methodist minister named John Lake. A land grant from the Canadian government which was aggressively pressing for (non-Indigenous) settlement on the prairies meant that after surveying the site in 1882, the first Temperance colonists arrived and settled in 1883 (Figure 1). They travelled by rail to Moose Jaw, and then overland for 250 km to the site of Saskatoon, a site chosen with advice from Chief Wapahaska (Whitecap) from nearby Moose Woods. The small settlement of Saskatoon, originally on the east side of the South Saskatchewan River (now the Nutana neighbourhood), served the agricultural homesteads orbiting it. Broadway Avenue, the main commercial street, overlapped with the Moose Woods – Batoche Trail for the in-town segment of it. During the Northwest Resistance in 1885, Round Prairie Métis and Whitecap Dakota First Nation peoples travelled past Saskatoon and north on the Moose Woods – Batoche Trail to join the Métis near Batoche, passing near to the site of the PMCA and at that time, the new homesteads of Temperance colonists.

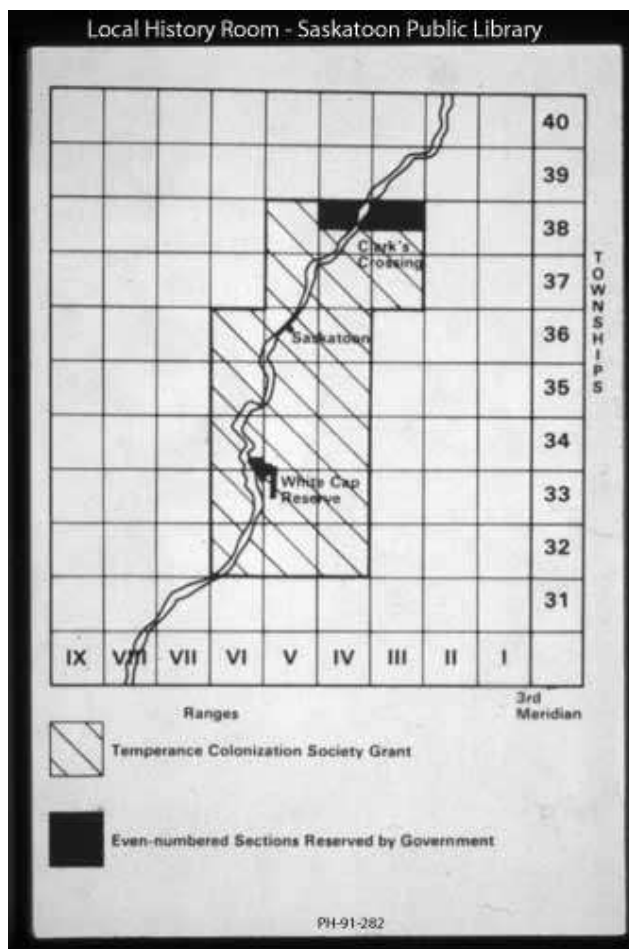

Figure 1: Map of Temperance Colonization Society land grant (Local History Room, Saskatoon Public Library)

The written memoirs of an early Temperance colonist, Barbara (Hunter) Anderson (Anderson and Anderson, 1972) are invaluable for understanding the early relationships between settlers and Indigenous peoples, from a settler's perspective. Her memoirs are all the more valuable for this paper given that her family's original homestead (on the Temperance Colonization Society land grant) was located only a short distance from the PMCA site. The following excerpt gives her view – as a 10-year old girl during her first summer since moving to the region – of the developing neighbourly relationships between settler and First Nations and tells an interesting story of hunting and household trade:

“During the summer of 1884 we were all very busy and on several occasions native Indians called on us. They were very friendly and had we been able to converse with them, would have enjoyed their comments. When they came to the house, they would come in quietly, without knocking, and were pleased when we were surprised. Once an Indian came in when we were eating dinner and Mother offered him the rocking chair to sit in. He sat down very carefully, but when the chair tipped backward he jumped to his feet, quite alarmed, and examined the chair from top to bottom, to see what had made it move. On another occasion an Indian [woman] came to our house, with a great armful of ducks on her arm. They had been hunting ducks at a nearby slough and had been quite successful. The Indians had not been used to having Rolled Oats and were very fond of it, cooked in many ways. They knew Mother had some, and the [woman] made signs to her that she wanted to trade ducks for oatmeal. Mother went to her bag of rolled oats and taking a bowl filled it heaping twice, and then took a small dip into the bag giving her only a little in the bowl the third time. When the [woman] saw this she picked out two of her largest Mallard ducks and a small Teal duck to give Mother in trade. Mother asked her for three Mallards, but she took the bowl and made signs that twice the bowl was heaped up and the third

time only a little in it. Thus the two large ducks and one small one was a fair exchange. Mother agreed and all were satisfied” (Anderson and Anderson, 1972, 57-58).

The first settler associated with the PMCA site itself was John Vance, followed in 1908 by Robert T. Luker, and then passing shortly after to Cleeve William Taylor, a bachelor who built a house on the land in 1909 (Enns-Kavanagh, 2008). All settlers to this point seemed to be short-term and doing little to transform the land, which was notably stony and irregularly configured along the river valley’s meandering edge. In 1916 William R. Hutchins received the patent for the land and he and his family lived there for some time. The Hutchins homestead has a significant heritage imprint on the PMCA site. For context, the population of neighbouring Saskatoon by 1916 was roughly 21,000. While William Hutchins appears to have died before 1936, and his wife Caroline moved away in 1937, what is believed to be their infant’s marked grave is still present on the PMCA site (Figure 2). Buildings from the Hutchins homestead were no longer on site by 1944 (Enns-Kavanagh, 2008). What remains today attributable to Taylor’s and then mostly the Hutchins’ homestead are depressions associated with their settlement of the site, a stone boat (i.e., a small sled with a box on top to haul stones out of the field by horse)(Figure 3), trail remnants linking the site to the Moose Woods – Batoche Trail, and the infant gravesite. The materiality and arguably a spiritual imprint from the Hutchins homestead combine with temporal pathways left from the era when colonial settlement was parceling and privatizing land tenure for homesteaders of European descent, displacing Indigenous communal hunting and patterns of life. Altogether this transitional period created texture to this place that is central to the PMCA’s heritage landscape (Adams *et al.*, 2001; Harvey, 2015) and vital to the public memory of the Saskatoon city-region (Hayden, 1995).

The Ranch – a country place cherished by the Lamarsh family (1945-1963)

MacDermid Lamarsh is one of Saskatoon’s oldest law firms and when Archie Lamarsh joined the practice in 1930 the city and province were entering a decade of depression and drought, the most difficult in Saskatchewan’s history. According to his son, Jack, Archie Lamarsh was a farm boy at his core, and though his ambitious law practice in Saskatoon required an urban base, which he and his family had in their home at 314 – 9th Street East, Archie was determined not to raise his family entirely in an urban setting (Lamarsh, no date). Following the difficult economic period of the 1930s, and then WWII, Archie Lamarsh bought from the Hutchins family estate in 1945 the land parcel that had been their homestead since 1916 (Enns-Kavanagh, 2008). By 1945 Saskatoon’s population had reached roughly 45,000 people.

Archie contracted a friend and client of his, a retired Scottish joiner, to build a log cabin which took a couple of years to build at a modest pace, all the while enjoying the beautiful landscape (Lamarsh, no date). One wall of the cabin had built-in double bunk beds; there was a “huge natural stone fireplace and a beautiful pine dining table which could seat 20 people at a time” (Lamarsh, no date). Archie and his family would affectionately call this land outside the city, and the cabin on it, ‘the Ranch.’ Jack’s recollection of his and his sisters’ place-connection to the Ranch in their upbringing reveals the magical impact of this site overlooking a beautiful bend in the South Saskatchewan River with silhouettes of Saskatoon’s skyline in the distance; note also the reference in Jack’s recollection below to the riverbank spring, a persistent feature from the time when it would have been a stop for travellers along the Moose Woods – Batoche Trail.

“We kids came to love the Ranch as my father did. The riverbank provided wonderful hideouts, trails and play areas. We could watch the crows and magpies build their nests and raise their noisy youngsters in the spring and summer. A prodigious riverbank spring was plumbed by my father with an old sunken barrel and stone sluiceways. In addition to providing a bountiful water supply, it attracted all kinds of birds and animals for us to

observe. The river provided fishing for goldeye and periodically we would see a giant sturgeon breach in midstream” (Lamarsh, no date).

To capture some of the beauty of the place, in 1948 Archie asked his client and friend Robert Newton Hurley, a watercolour painter that was rising to fame in Saskatchewan, living in the nearby town of Sutherland (annexed by Saskatoon in the late-1950s), to come out and create a painting of the Ranch (Lamarsh, no date). Jack recalls watching the artist work and enjoying his stories about his own childhood in England, before immigrating to Canada in the 1920s. The Hurley painting became a treasured family heirloom for years afterward in Lamarsh homes.

It would seem that the Ranch was a special nexus of hearth and cosmos (Tuan, 2001) in the sense of place held by the Lamarsh family in the Saskatoon city-region, venturing from their home in one of the most dense and ‘urban’ neighbourhoods in Saskatoon into the nearby regional landscape with a natural setting that inspired awe and a sense of grandness. In 1963 when Archie Lamarsh sold the site to the Roman Catholic Diocese of Saskatoon, it was with 18 years of imprinting between the natural landscape, its non-human and human patterns, material and intangible (Harrison, 2013), building depth and complexity into the texture of this place (Adams *et al.*, 2001). Like the Hutchins family before them, the Lamarshs left the land mostly unbroken and in its natural state, to become similarly inspiring for the next stewards of this site, adding to its place memory (Hayden, 1995).

Maryville – a retreat for congregations of Catholic women religious (1963-1995)

The Roman Catholic Bishop of Saskatoon, Francis Klein, after recovering at St. Paul’s Hospital from an acute heart attack the year before (Robertson, 1982), wrote to the Sisters Superiors of all the congregations in Saskatoon on May 8, 1963, indicating that he had acquired the property that would become Maryville, named after Mary, mother of Jesus (Klein, 1963). The Episcopal Corporation of Saskatoon had purchased ‘the Ranch’ from Archie Lamarsh with the Lamarsh log cabin still on it (Figure 4). Bishop Klein blessed the land (Stengler, 2004) that would be used “so that the Sisters of the diocese might have a place, close to the city, where they could go for a few hours or even days to enjoy the country quiet” (Klein, 1963, 1), an idea suggested to him by Father (later Monsignor) John Robinson. He described the property as “undeveloped”; “[h]owever, there is a club house on it, lots of stone, wild grass, cliffs, some bush and a spring of fresh water” (Klein, 1963, 1). Bishop Klein called a meeting to be held five days later, for all Sisters Superior, each with one companion, to attend a meeting at the new ‘summer resort’ to see it and brainstorm ideas on how to best appoint it (Diocese of Saskatoon, 1963). Roughly 40 Sisters attended. Dinner was served. At that meeting the Bishop conveyed his view that the Sisters, having done so much for the Diocese, deserved a retreat space specifically for them as a thank you, remarking that they rarely get to fully relax and very “seldom enjoy the beauty of nature” (Diocese of Saskatoon, 1963, 1). Also important to this endeavour was the sense that the communities of Sisters were working typically in isolation from one another, and this place was to bring them together. It was for Sisters of all the congregations in the Saskatoon diocese. As context, the nearby city of Saskatoon’s population was roughly 100,000 people in 1963.

Figure 4: Statement of sale – Archie Lamarsh to Episcopal Corporation of Saskatoon (Roman Catholic Diocese of Saskatoon archives)

Incorporating the log cabin (referred to above as a club house by the Bishop) that Archie Lamarsh had built in the 1940s as their central ‘Common Lodge’ at Maryville, each religious community of women was encouraged to have their own cabin built or moved to the site, if they wished. Those that did not were always welcome to use the Common Lodge which, as noted in the previous section, had bunk beds built into one wall, a stone fireplace, and a large table to seat 20 people. At that first meeting they talked about a swimming pool being built shortly, a chapel, a road to the cluster of cabins, water system, gas, and eventually electricity (Diocese of Saskatoon, 1963). Later on phone service was added to some cabins, but at the start, a two-way radio system from the Common Lodge was used. The site was “strictly private for the Sisters use” (Diocese of Saskatoon, 1963, 2). If you imagine at the time, in the early 1960s, Sisters wore full habits and a commitment to modesty made recreation in public places difficult or impossible (Figure 5). A private retreat like this was wonderful, in their view. The minutes of that first meeting with Bishop and Sisters on site sets out a question for all to ponder: “What name should be given to the place? Not a worldly one.” And the site itself, as captured in the closing line of those minutes, “is beautiful....a corner of heaven!” (Diocese of Saskatoon, 1963, 2).

Figure 5: Group of Sisters at Maryville (Stengler, 2004, 40)

Letters and cards of thanks came in throughout the summer of 1963 as Sisters expressed their gratitude and captured some of the initial excitement of the time (Figure 6). The place was referred to variously as a retreat, camp, resort, country house, but did not have a name quite yet. The first suggestion of a name seems to be in a letter from the Sisters of Sion in July, where they suggest “Maryvale” (Edeltrude, 1963, 1). In the letter they note that joy from the swimming pool has “gone beyond all expectation.” In another letter from St. Mary’s Convent (Catherina, 1963, 1), the Sisters write to tell Bishop Klein of “the wonderful evening we spent and how we enjoyed the balmy air and beautiful view of the winding river.” Another note from an older Sister Superior talks about how much the younger Sisters enjoyed the Common Lodge and exploring the natural beauty of the site. By 1964 it was referred to clearly as ‘Maryville’, and in its statement of accounts, you can see that volleyball, basketball, baseball, swimming, and a barbeque were all part of the recreational experience. There were at least 14 religious communities of women using Maryville, some now with their own cabins on the site. There were reportedly six cabins moved onto the site for different congregations of Sisters, plus a chapel, and the Common Lodge built by Lamarsh and his retired Scottish joiner friend (Figure 7). A shower house was built. The Maryville Association Executive was struck, with a President, Treasurer and several other Directors, all Sisters from different congregations in the Saskatoon diocese (e.g., Maryville Association Executive, 1967). And the Executive Director was Monsignor John Robinson. Maryville would typically open for the summer in early June and then close in early September. Three horses were at Maryville for horseback riding, during some years, which was exceptionally popular among some of the Sisters. Time and again, picnics, potluck dinners, sing-songs with musical instruments, Mass and celebrations in the chapel, and organized group events among the congregations of Sisters were advertised and formed the seasonal highlights (Figure 8).

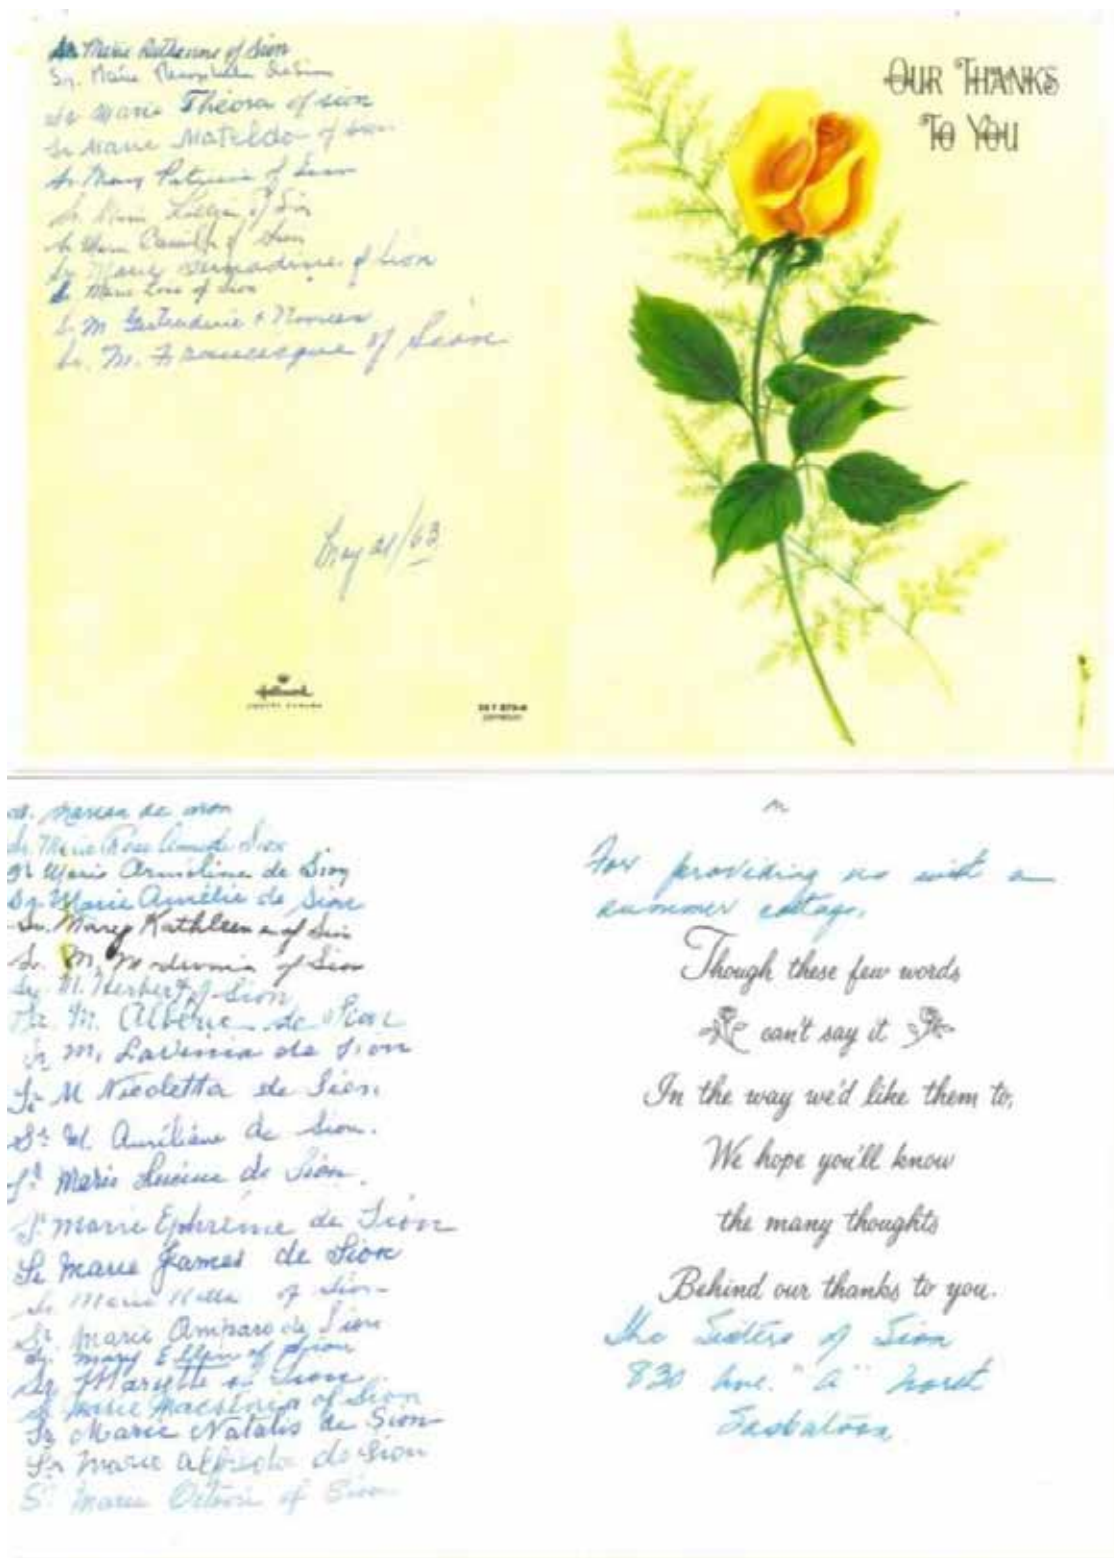

Figure 6: One of several thank you cards/notes addressed to Bishop Klein from congregations of Catholic women religious (Roman Catholic Diocese of Saskatoon archives)

Figure 8: Handbill advertising one of the regular community gatherings at Maryville (Roman Catholic Diocese of Saskatoon archives)

The Maryville Chapel was renovated in 1977, and improvements were made to the Common Lodge in the Spring of 1978 (Diocese of Saskatoon, 1978). In the early 1980s the Sisters of the Saskatoon diocese were growing concerned about the City of Saskatoon's urban expansion plans and how these would impact the Maryville site (Stang, 1981, 2). After some inquiries with the City, they were assured that the growth plans for that northeast area were 25 to 50 years out into the future. The Sisters re-visited the original vision for Maryville from 1963, pondering, now in the 1980s, the prospect of opening it to lay groups for weddings, retreats, and charging for use of the facilities. Invoking the original purpose of Maryville articulated by the now both deceased former Bishop Klein and Monsignor Robinson, and the group of Sisters Superior at that critical first meeting in May 1963, consensus was reached among the current Bishop, James Mahoney, and the Sisters, that Maryville was not set up to make money, and that "[i]t should be maintained as **a summer resort for our sisters**" (Stang, 1981, 2).

By the early-1990s, a high level of vandalism was causing terrible concern and the 1994 season was an important one for taking a big picture look at the future of Maryville. A letter in April 1994 calls for a meeting of the Sisters in the Saskatoon diocese to create "a plan for where to go next" with the future of Maryville (unknown author, 1994). It appears that the meeting resulted in some decisions around actions to be taken because in the late-summer and Fall of that year a trailer was moved onto the site to house a year-round

caretaker, a new garage for storage of site equipment was constructed by the Saskatoon diocese at Maryville (AMEC Earth and Environmental, 2008), the last building to remain on the site, still present in 2019, and the shower house by the pool was upgraded. It seemed that this new investment signalled the renewed determination to keep Maryville as an operating summer retreat for the Sisters of the Saskatoon diocese. But Bishop James Mahoney, who had been a champion of the purpose of Maryville according to the vision of his predecessor, passed away in 1995, and shortly after he died, an administrator of the Saskatoon diocese was put in place to oversee operations of the Saskatoon diocese until a new Bishop was appointed in 1996. Under the temporary diocesan administrator, Father Leonard Morand, Maryville was closed permanently in 1995 during the brief interregnum period between Bishops. The diocese held the land for another 12 years before selling it to the MVA, in March 2007. Father (then Monsignor) Leonard Morand passed away three months after the sale of land to the MVA. Remnants of the basketball court and the grotto for the shrine, which was a statue of Saint Joseph, are present on the site (Figures 9 and 10).

The congregations of Catholic women religious from the Saskatoon diocese were important stewards of this landscape for several decades, and in their enjoyment and care of this environment, created a sense of place at the PMCA site rich with material and spiritual texture (Adams *et al.*, 2001). Part of the heritage of this site is embodied by the immaterial blessing of it, the motivation behind creating a community of congregations here, and the dialogical process of making decisions, revisiting the purpose of this community retreat, and exercising care for it (Waterton and Smith, 2010; Harrison, 2013).

Toward the conservation of public memory – Applying a connectivity ontology and dialogical process

In 2007 the MVA bought the former Maryville site, by then closed for 12 years, from the Roman Catholic Diocese (Episcopal Corporation) of Saskatoon, aiming to link the site eventually to its network of river valley trails, with interpretive signage, and offer “environmental education and recreational programming that promote conservation and stewardship” (MVA, 2009). In 2009 the MVA named the site after its first and longest-serving board chair, Margaret (Peggy) McKercher. McKercher, a prominent and well-respected community leader in Saskatoon, served the inaugural role as MVA chair from 1979 until 1995 (coincidentally the year Maryville was closed). When MVA purchased the land the resource conservation manager at the time, John Gerstmar, remarked in the Saskatoon StarPhoenix newspaper (2007, A6) that “[i]t’s an absolutely beautiful natural area along the bank. There’s a little bit of disturbance, but really about 90 per cent of it is in its natural state.” The population of Saskatoon was around 200,000 in 2007, and new neighbourhoods were being planned and opened up nearer than ever before to the site, though still a significant distance away.

The concern raised by the Sisters of the Saskatoon diocese in the early 1980s about the risk to the Maryville site from encroachment of urban development was prescient and will materialize over the next decade according to the City of Saskatoon’s growth plan for new neighbourhoods referred to in its University Heights Sector Plan, unless the City’s leadership alters the path of future development. The City has already recently opened a new high capacity roadway and bridge through the ecologically sensitive native grasslands habitat of the Small

Swale and Northeast Swale, not far from the PMCA site. The Province of Saskatchewan has located a right-of-way to build a new Saskatoon Freeway as a city bypass route in roughly 10 years which would also cross the Swale ecosystems. Yet even in the face of these challenges, the PMCA holds out the possibility for a site of great heritage significance for Saskatoon and the surrounding region. Its natural integrity, beauty, and humble human and non-human interaction with the prairie landscape that is still part of a functioning ecosystem intact after more than 10,000 years, has generated a spirit of place worth conserving. The critical role that heritage can play is precisely to jump into the midst of society's pressing challenges, such as the need to build stronger intercultural relationships between peoples, to arrest environmental degradation, and to generally draw clearer connections between culture, environment, history, spirituality, and peoples.

This heritage landscape has been created by the coming together of the land, human activity, reverence, and joy – a stopping point for repose at the water spring, hunting grounds and part of the larger homeland and territory of Indigenous communities, a site where new land tenure laws were imposed by the European settler government, displacing Indigenous peoples, given local effect by the Temperance Colonization Society in their land grant. The PMCA was home to the Hutchins family, cherished and protected by the Lamarsh family, a recreational and blessed retreat for the Catholic Sisters of Saskatoon, and now under the care and stewardship of the MVA, a publicly-funded local conservation organization focused on the South Saskatchewan river valley, protecting and interpreting its (natural and cultural) heritage. As if to come full circle and reconnect more powerfully with the Indigenous culture that forms part of the deepest texture of this place – a foundational element for millennia – the MVA recently entered an agreement with the Saskatchewan Health Authority to have Elder and Métis Knowledge and Ceremonial Keeper, André Letendre, from the Batoche community, conduct Sweat Lodge ceremonies at the PMCA over (at least) the next year.

At a Pipe Ceremony led by the Elder, André Letendre, to start this new relationship with the MVA staff and board of directors in May, 2019, I took away from the ceremony a message of the importance of unifying the region's peoples, worldviews, and futures, in a shared reverence for the 'great mystery' shared by peoples of different cultures. Guided by the societal goals emanating from Canada's TRC, and given the nature of the PMCA's layering of natural diversity, First Nation, Métis, European settler, urban and rural connections, Catholic faith, Indigenous ceremony, and MVA's mission to conserve and educate about the heritage of the river valley landscape, it would seem that a powerful heritage landscape is presenting itself for conservation and interpretation. Guided by a connectivity ontology and dialogical process (Harrison, 2013), an enduring need to conserve the public memory (Hayden, 1995) particular to our shared hearth in the cosmos (Tuan, 2001), and to address our most pressing environment and society issues (Winter, 2013), the potential is great for the MVA to work with Indigenous nations, City of Saskatoon, Province of Saskatchewan, Roman Catholic diocese, and local citizens to protect, interpret, and program the continuity of the site's heritage. At top of mind is that, in doing so "[h]eritage is not a passive process of simply preserving things from the past that remain, but an active process of assembling a series of objects, places and practices that we choose to hold up as a mirror to the present, associated with a particular set of values that we wish to take with us into the future" (Harrison, 2013, 4).

Abstract: The title of human-habitat historical environment is awarded to traditional human settlements under specific economic, political, cultural and technological conditions. Such environment has dual attributes of historical protection and community life, and its sustainable protection has an important impact on urban development and resident life. By analyzing the problems in the protection of Chinese human-habitat historical environment. Issues touch on the neglect of community life in protection action, the ignorance of the big environment background in protection perspective, the lack of regional considerations in development strategies, and the implementation force is dominated by the will of the government, as well as the deficiency of dynamic management mode. Then, through in-depth interpretation of UNESCO's proposals on environmental protection of historic cities, drawing on the experience of historical environmental protection in HUL pilot cities, and based on the concept of sustainable development, this paper puts forward the transformation paths of Chinese human-habitat historical environment. This paper focuses on the discussion of the two settlement types of traditional villages and the Ancient City of Pingyao(ACP) in Shanxi Province. The main paths include: protecting objects from focusing on the heritage protection to considering both heritage protection and community life; protecting perspectives from cultural relics protection to protection of urban environment floor; protecting forces from relying on government to multi-force participation of the whole society; and protecting management from static management system to sustainable dynamic planning management. By protecting, renovating and improving the livability of the human-habitat historical environment, the sustainable development of the urban historical environment is gradually realized. The paper is intended to provide experience for sustainable protection of the human-habitat historical environment in China.

Keywords: transition; human-habitat historical environment; traditional villages in Shanxi Province; the Ancient City of Pingyao

1 Introduction

In recent years, the environmental problems brought about by the rapid urbanization process have attracted more and more attention. Among them, the urban historical environment, as a collective memory of human beings^[1], is facing tremendous pressure and challenges. "Human-Habitat Historical Environment" refers to the overall space environment composed of cultural heritage, place environment and community life, which has dual attributes of historical value and community life value. At present, China has entered a comprehensive

transformation stage from traditional to modern^[2], and the transformation and development of China's "Human-Habitat Historical Environment" is an irreversible trend of the times. In this context, "Sustainable Development" and "Historical Urban Landscape (HUL)" have gradually become hot topics in the field of heritage protection in China^[3]. The former requires the protection and sustainable management of existing resources and urban heritage, while the latter, as a holistic and dynamic concept in a new perspective, provides an opportunity for the interdisciplinary exploration of "Human-Habitat Historical Environment"^[4] and a new reference paradigm for the sustainable protection of city heritage in China.

2 Human-Habitat Historical Environment

2.1 Overview of Human-Habitat Historical Environment

"Human Settlement" refers to various types of human settlements and environments in cities, villages and towns^[5]. Among them, "the city is the material framework of daily family and economic activities, as well as an environment of concern for more meaningful actions and nobler impulses of human culture" (Lewis Mumford, 1961). "Human Settlement Science" was founded by Doxiadis and systematized by Wu Liang-yong and others in China^[6] (Figure 1). It is a science focusing on the relationship between human beings and the environment, and also an interdisciplinary group of disciplines, such as geography, environment and economy, which are dominated by architectural science^[7].

"Historical environment" refers to the overall historical environment landscape composed of historical buildings, historical streets and historical context, which represents the human characteristics of the region. While the "Human-Habitat Historical Environment" emphasizes the important role of community life in the historical environment landscape. It is the environmental space created by human beings in the past under specific economic, political, cultural and technological conditions. It has dual attributes of historical protection and community life.

"Human-Habitat Historical Environment" can be roughly divided into two clusters: one is "Human-Habitat World Heritage", whose "outstanding universal value" is so rare that it transcends national boundaries and has universal significance for the present and future of mankind (United Nations Educational, Scientific and Cultural Organization); the other is the "General Human-Habitat Heritage", such as traditional villages, ancient villages, historic and cultural towns and famous villages, historic and cultural blocks and other historical environment areas with "life attribute" and "heritage attribute".

2.2 Transitional Development of "Human-Habitat Historical Environment"

With the acceleration of urbanization in the world, more and more cities are facing great threats. The protection and development of urban historical environment are facing major challenges. The transformation and development of urban historical environment has become an irreversible trend of the times. In this context, the international community has carried out in-depth discussion on the transformation and development of urban historical environment, and eventually issued the "Recommendation on the Historic Urban Landscape" in 2011, forming a new concept of urban historical environment transformation and development - "Urban Historical Landscape", and then extended and promoted the connotation of its methods. Historic Urban Landscape (HUL) is a renewed and dynamic method of managing heritage resources. Its connotation emphasizes the importance of

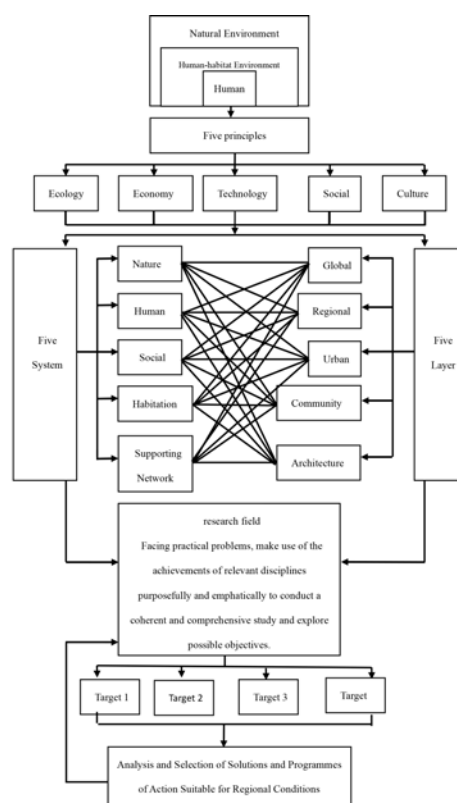

Figure 1. Basic Research Framework^[6].

the sustainable protection and shaping of the historical environment of ordinary daily life landscape, and emphasizes the results of the "layering" a formed by the superposition of other different "layers", such as the natural "layer" and the humanistic "layer".

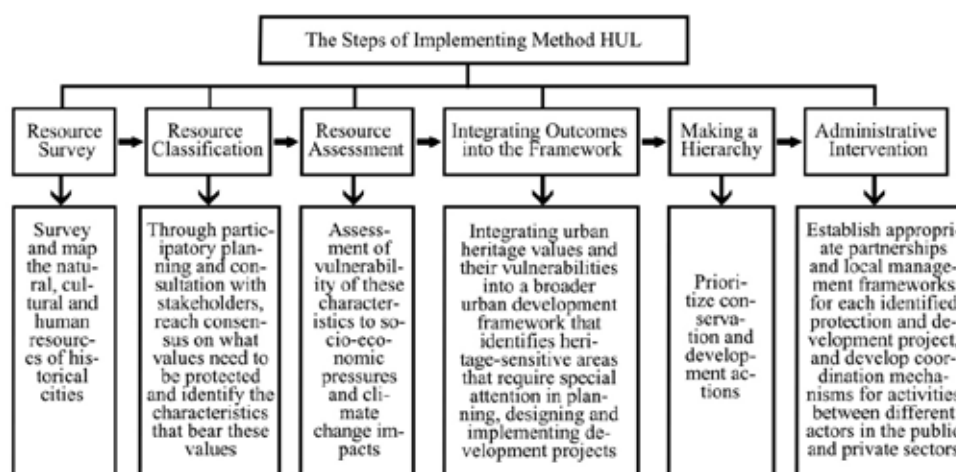

Figure 2. Implementation Steps^[8].

HUL international pilot projects have been actively launched in Africa, Europe, North America, Latin America and the Asia-Pacific region. Up to now, more than 10 cities have joined the project, which has attracted many attentions from the field of international heritage protection. The specific practice of these pilot cities in the application of HUL concepts and methods deserves summary, reflection and reference.

Table 1 Summary of other pilot cities in the Asia-Pacific region^[3]

Country	Ecuador	Tanzania	Australia
City	Cuenca	Zanzibar	Ballarat
World Heritage Site	Yes	yes	no
time	2015	/	2013
Application Scope of HUL	Historic Center and Its Surrounding Areas	Ng'ambo area	Bararett City
Major challenges	Excessive urban development; gentrification; immigration; threat to heritage buildings; tourism challenges; abandonment of modern heritage; real estate investment; transportation; low-quality development and expansion of contemporary architecture	World Heritage Sites Lack of Linkages with Regional Scope; Population Growth Too Fast; Buffer Zone Protection Inadequate; Policy Guidelines Insufficient	Massive population growth; expansion of historic urban areas; climate change
Application of HUL Toolbox			

Public Participation Tools	Cultural Mapping; Seminar on Citizen Participation	Cultural Mapping; Non-material Heritage Mapping; Community Participation; Stakeholder Participation; Vision Conference; "People Decide Planning"; Mutual Partnership	Cultural Mapping; Local Participation; Online Tools (e.g. HUL Portal Network); Advisory Committee; Information Package; Work Camp; Establishment of Heritage Awards; Media Participation
Knowledge and planning tools	Kunka History Center Protection Planning; Background Research and Detailed Research; Basic Information Table; Establishment of Database; Drafting of Proposals	Local Planning (LAP); UL Analysis of Planning Policy Guidelines (PPG); Complementarity of Research and Design; Heritage List	Visualization of Bararete Project; Bararete Heritage Database
Regulatory system	Classified Protection; Handbook of Excellent Practice Cases	National Space Development Strategy; Zanzibar Structural Planning	Bararete Strategy; Bararete Planning Plan; Statutory Planning and Implementation; Heritage Additional Mechanism; Community Participation Policy
Financial instruments	foundatin	Dutch Government Subsidies	Jointly Protect Our Heritage - Subsidies; Bararete Heritage Restoration Fund - Subsidies

It can be seen from the table that the application of the suggested toolbox has been taken into account in the application of the HUL method in the three cities, but each has its own emphasis. In the public participation tools, the production of cultural maps has been used, and different levels of public participation have been added; the establishment of relevant databases has been emphasized in the knowledge and planning tools; and in the regulatory system, the main consideration is the establishment of relevant databases. The application of the overall strategy and the means of hierarchical protection; in the financial instruments, government subsidies and related fund subsidies are the main sources of funds. Through tracking and evaluating the specific application of HUL method in different cities, it can effectively guide the follow-up HUL method related practice projects.

3 The Chinese Human-Habitat Historical Environment from the perspective of the Traditional Villages and the Ancient City of Pingyao in Shanxi Province

"Human-Habitat World Heritage" and "General Human-Habitat Heritage" are two important settlements in the "Human-Habitat Historical Environment". As the saying goes, "Five thousand years of civilization see Shanxi". Shanxi is one of the important birthplaces of the Chinese nation. For thousands of years, our ancestors have created brilliant civilizations in this hot soil and left a large number of historical relics. The typical representative of the "General Human-Habitat Heritage" is the traditional villages in Shanxi Province and the typical representative of the "Human-Habitat World Heritage" is Pingyao Ancient City. There are a series of problems in the process of its protection and development. Although it cannot fully represent the protection experience of all types of Chinese

“Human-Habitat Historical Environment” , its changing trend and challenges are of great significance to the protection of the historical environment of human settlements.

3.1 Overview of Traditional Villages in Shanxi Province

Shanxi Province is located in North China (Figure 3), on the Loess Plateau, adjacent to Hebei in the east, with Taihang Mountain as a natural barrier. The Yellow River in the West and south, facing Henan and Shaanxi, crosses the Great Wall in the north and adjacent to Inner Mongolia Autonomous Region. Its special geographical location makes Shanxi Province a military strategic location since ancient times, and its complexity is changeable. Regional environment, unique location conditions and strong historical background make Shanxi Province a major province of cultural relics in China (Figure 4), known as the cradle of Chinese civilization and the Museum of Ancient Chinese Art. So far, there are 129 Chinese traditional villages and 239 Provincial Traditional Villages in Shanxi Province (Figure 5). Among these traditional villages, the traditional villages dwelling mainly in Ming and Qing Dynasties are the most characteristic and representative. The space layout, architectural features and carving art of these courtyards are of great significance to the study of traditional dwelling buildings in northern China. The historical culture behind them and the social structure formed through historical accumulation constitute a common structure. Shanxi's urban characteristics and cultural connotations. Its complex and changeable geographical environment, unique geographical conditions and strong historical background make Shanxi Province a major province of cultural relics in China, known as the cradle of Chinese civilization and the Museum of Ancient Chinese Art. So far, there are 129 Chinese traditional villages and 239 Provincial Traditional Villages in Shanxi Province. Among these traditional villages, the traditional villages dwelling mainly in Ming and Qing Dynasties are the most characteristic and representative. The spatial layout, architectural features and carving art of these courtyards are of great significance to the study of traditional residential buildings in northern China. The historical culture behind them and the social structure formed by historical accumulation constitute the urban characteristics and cultural connotations of Shanxi (Figure 6-8).

Figure 3. Location of Shanxi Province in China.

Figure 4. The Distribution Characteristics of Chinese Traditional Villages among the Provinces^[9].

Figure 6-8. Photographs of Traditional Villages in Shanxi Province^[11].

Figure 5. Distribution and Types of Traditional Villages in Shanxi Province^[10].

Traditional villages in Shanxi Province, as the representative of "general human settlements heritage", do not have the tremendous impact of tourism brought by the name of "World Heritage", but in the context of rapid urbanization, the deterioration of their natural and artificial environments, the conflict between modern lifestyle and traditional living environment, the tremendous impact of industrialization and urbanization on traditional settlements and the large scale, rich connotation and complexity of the present situation hinder the sustainable development of local architecture and its historical environment (Figure 9-16).

Figure 9-16. The current situation of environmental deterioration in some traditional villages in Shanxi Province.

3.2 Overview of the Ancient City of Pingyao

Pingyao County, located in the central part of Shanxi Province (Figure 17), is a large cultural relic County in Shanxi Province. It has more than 300 historical and cultural relics. Among them, the Ancient City of Pingyao

is the most representative and typical. In 1986, the Ancient City of Pingyao was named "National Historic and Cultural City", and in 1997, it was named "World Cultural Heritage", which is the most well-preserved ancient city in Chinese "Human-Habitat Historical Environment". It preserves the historical form of the county-level cities of the Han nationality in central China during the Ming and Qing Dynasties (14-20th centuries) (Figure 18-19). It has unique defense system features, axis-like functional layout features, street and lane pattern features that continue the ancient Chinese Lane system, space courtyard pattern of traditional northern residential courtyards and a large number of intangible cultural heritage and local traditional cultural practices, Pingyao has rich tourism value because of its unique ancient city cultural landscape, which attracts people from all over the world to come and watch (Figure 20-21).

Figure 17. Location of Pingyao in Shanxi Province, China.

Figure 18-19. Maps of Pingyao County Town in Ming and Qing Dynasties^[12]. Figure 20-21. Pingyao Ancient City Wall and Traditional Residence^[13].

In recent years, due to the development of tourism, Pingyao ancient city walls and public buildings have been well protected by the cultural relics department, but as the background of Pingyao ancient city, many traditional residential courtyards have been damaged, collapsed or even rebuilt (Figure 22-25). Large-scale tourism development has made a huge impact on the historical environment of the ancient city of Pingyao. The loss of the characteristics of the ancient city and the social changes with residents as the core all threaten the authenticity and integrity of the world heritage.

Figure 22-25. Rebuild and Waste of Branch Courtyards in Pingyao Ancient City.

3.3 Problems in the Action of Chinese Human-Habitat Historical Environmental Protection

With the accelerated development of urbanization in China, the phenomena of "constructive destruction", "protective destruction" and "creative destruction" prevail in the development process of human settlements historical environment, which often destroys urban texture, human settlements environment and urban cultural foundation while demolishing historical buildings. "Constructive destruction" has always been a major threat to the protection of urban heritage in China, and some urban development projects violate the protection laws and regulations and related management regulations, causing irreparable disasters to the historical environment; "Protective destruction" refers to the phenomenon of ancient city revival and old street revival, which has emerged in recent years. It has become a large-scale demolition and construction act with cultural signboards. The "human settlements historical environment" is mostly used to develop thousands of uniform commercial tourist sites with cultural packaging. The living needs of the aborigines are not satisfied, and the original social system no longer exists; "Creative destruction", created by the collusion of capital and power, has sprung up like mushrooms^[5]. The main problems in the process of protection of Chinese residential historical environment can be summarized as follows: protection action ignores community life, protection perspective ignores environment background, development strategy lacks regional consideration, implementation force is dominated by the will of the government, and management mode lacks dynamism. The protection of "Human-Habitat Historical Environment" should not solidify the current situation of historical environment, but maintain the harmonious, unified and dynamic and sustainable development of natural environment, human environment, historical environment and community environment.

4 Strategies for the Transitional Development of Chinese Human-Habitat Historical Environment

The HUL method emphasizes the dynamic protection of the urban historical environment from a new perspective, especially provides the overall idea and huge space for the development of scientific development, human development and human-land co-prosperity for the human settlements historical environment in the process of transformation and development. European urban historical environmental protection experience and HUL international pilot project practice experience have important reference significance for the transformation and development of Chinese "Human-Habitat Historical Environment"^[14]. Therefore, in view of the related problems in the development process of Chinese "Human-Habitat Historical Environment", based on the concept of sustainable development and the reference of international experience, this paper puts forward the following transformation path of Chinese "Human-Habitat Historical Environment" according to local conditions.

4.1 Protection Object Transition from "focusing on heritage protection" to "giving consideration to both heritage protection and community life"

The continuity of culture and place spirit (sense of place) based on the HUL method emphasizes the relevance value of heritage protection, especially community value. It is also one of the "5C Strategic Goals"ⁱ advocated by the World Heritage Committee and supported by the international community. Both "General Human-Habitat Heritage" and "Human-Habitat World Heritage" have dual attributes of historical heritage and community life. Therefore, in the process of protection, we should not only consider the authenticity of historical heritage and the

integrity of historical environmental quality, but also pay attention to the continuity of residential life and the continuity of local sense of place. The HUL method emphasizes the importance of economic, social and cultural factors in promoting the formation of historical environment, focuses on the importance of ordinary daily life for urban landscape, and attaches importance to the role of ordinary residents in the formation and protection of human settlements historical environment.

Urban planning has the responsibility to protect the city's historical features and space spirit. The old houses and ordinary daily life of ordinary residents are the direct records of the city's public history and the basis of maintaining social relations network. Governments at all levels, especially local governments, have the responsibility to protect the city's public history and collective memory, and actively carry out field surveys, economic assessment, policy formulation, planning and implementation, and encourage public participation.

4.2 Protection Perspective Transition From "Single Protection of Cultural Relics" to "Protection of Urban Environment Base Plate "

The HUL method emphasizes the construction of an all-round and multi-level heritage protection system. From the perspective of transformation, the sustainable protection of Chinese "Human-Habitat Historical Environment" should establish an all-round and multi-level protection system starting from "point", connecting with "line" and forming a "face", which is a protective base plate. Starting from "point", which required to protect the authenticity and integrity of cultural protection units, historical buildings, industrial heritage, ancient and famous trees at all levels; connecting with "line", which emphasizes the continuity protection of historic and cultural blocks, historic walls, traditional villages, streets and lanes, and important river systems, with lines crossing points and lines forming planes; forming a "face", which refers to the protection of the whole urban environment base plate, extending the protection to the level of regional human environment and natural geographical environment, and continuing the cultural context of the times. The drawing of cultural maps in HUL method emphasizes the comprehensive investigation of "points", "lines" and "all-round". On this basis, the priority order of heritage protection and development can be determined through the participation of all parties in the evaluation, so as to promote step by step and protect the heritage in an all-round way.

In China's existing "cultural relics protection unit - historical and cultural cities (towns)" protection system, the operating mechanism of the environment base plate is not mature, while paying attention to physical space protection, we should also pay attention to the integration of the basis of environmental resources. The environmental landscape in the historic city of human settlements is the basis of its "historic" presentation. Combing and incorporating the natural landscape into the heritage protection system is also very conducive to the management of the government.

4.3 Protection Force Transition from "Depending on the Government" to "Multi-Forces Participating in the Protection of the Whole Society"

The HUL method emphasizes the participation of multi-stakeholders and advocates the establishment of a platform for social participation. In the process of sustainable development of " Human-Habitat Historical Environment "in China, we should not only attach importance to the active control role of the government as a "tangible hand", but also give full play to the role of social forces as an "invisible hand". By combining the favorable elements of all sectors of society, data collection and analysis of urban historical environment are carried out in various aspects, so that stakeholders can clearly define the important value of urban cultural heritage, and then formulate a variety of long-term feasible mechanisms, such as government-led, citizen participation and so on, so as to promote the comprehensive protection of diversity in urban historical environment. The model of "multi-force participation in the protection of the whole society" builds a comprehensive platform in line with the environment of heritage sites and social activities, facilitates effective dialogue among different subjects, and at

the same time meets the protection needs of various sectors of society. It is an important force for the sustainable protection of Chinese "Human-Habitat Historical Environment".

4.4 Protection Management Transition from "Static Management System" to "Sustainable Dynamic Planning Management"

HUL method pays attention to the importance of urban historical context continuation for urban historical environmental protection. In the Recommendation on the Historic Urban Landscape, it emphasizes that "the urban historical environment is the accumulation of values created by the connecting cultures and existing cultures in history, as well as the accumulation of traditions and experiences" ⁱⁱ, while recognizing the "dynamic nature of living towns". The HUL method encourages urban development and renewal, but emphasizes a dynamic and sustainable planning, which actively plans the sustainable development direction of the city according to the current situation of urban development, urban characteristics, urban historical value and so on. As Kevin Lynch said, "Managing and effectively utilizing the changes in historical sites for present and future needs is better than a rigid respect for the sacred past." The core of urban planning management is to effectively manage "change". It is neither fixed nor laissez-faire. Its key point is to take full account of the diversity and sustainability of historical cities. At the same time, it is necessary to improve the protection system, relevant laws and regulations, planning standards and urban planning system at all levels, and explore the dynamic and sustainable mechanism of planning protection management.

5 Conclusions

The method of urban historical landscape (HUL) not only emphasizes the protection of heritage itself, but also integrates and expands the elements of natural landscape, community life and regional conditions, which greatly enriches the scope and methods of historical landscape protection. Therefore, only when the environmental base is guaranteed and the development strategy covers a wide range of perspectives, such as broadening the object of protection, dynamic management, and the participation of the whole people in practice, can the sustainable protection and transformation of the "Human-Habitat Historical Environment" be finally promoted. It provides new experience for China's sustainable protection strategy in protecting objects, protecting perspectives, protecting forces and protecting management, and provides new ideas for improving the livability of "Human-Habitat Historical Environment" and realizing the sustainable development of urban historical environment.

Endnotes

- i. "5C strategic goal" is to enhance the *credibility* of the World Heritage List, ensure the effective *conservation* of the World Heritage Site, promote the effective *capacity building* of the States Parties and heritage sites, promote public awareness, participation and support for the protection of the World Heritage Site through *communication*, and strengthen the role of *community* in the implementation of the World Heritage Convention.
- ii. Article 8 of the *Recommendation on the Historic Urban Landscape*: Urban historical landscape is a city area created by the accumulation of cultural and natural values and attributes in history. It goes beyond the concept of "historical center" or "whole", including a broader urban background and its geographical environment. Article 11: The method of urban historical landscape aims at maintaining the quality of human environment, improving the productive utility and sustainable use of urban space while recognizing its dynamic nature, and promoting social and functional diversity. This method combines the goal of urban heritage protection with the goal of social and economic development. Its core lies in the sustainable balance between the urban environment and the natural environment, the needs of present and future generations and the historical heritage.

TRANSFORMATION OF ROADS' FEATURE PROTECTION: STATUS AND FUTURE THINKINGS OF SHANGHAI'S FEATURE- PROTECTED ROADS: BASED ON THE CASE OF YUYUAN ROAD IN SHANGHAI

YeYuan Zhou¹, XueYan Wang²

¹ College of Architecture and Urban Planning, Tongji University, 913525267@qq.com

² College of Architecture and Urban Planning, Tongji University, 501332552@qq.com

Abstract: During the decades of the formation and development of historic roads in Shanghai, the urban connotation has different traces in different times. Feature-protected roads are one kind of urban heritage because they have the characteristics of urban form and urban culture. However, in the process of protection, the work of protecting feature-protected roads has been confronted with certain difficulties due to the imperfection of the theory and the technology. This paper tries to answer the question what are the realistic problems and dilemmas faced by the feature-protected roads under the background of rapid development and transition of the city? And what aspects should be focused on in the protection work? It combs the basic characteristics of the relevant planning of Shanghai feature-protected roads and analyzes the requirements of the management and control of feature-protected roads in Yuyuan Road Historical and Cultural Area and the status of its protection, aiming to explore the highlights and problems in the protection process. Finally, this paper tries to put forward the optimization direction aiming at the problems in the protection work, which can provide the protection of historical landscape and the continuation of cultural tradition under the concept of shareable development.

Keywords: feature-protected roads; Yuyuan Road in Shanghai; planning control; protection status

1. Introduction

Shanghai is one of the national historic and cultural cities. It has rich history and culture, gathers many excellent modern buildings and revolutionary histories, and forms a unique urban style. In order to strengthen the protection of style and features, in July 2002, Shanghai promulgated *the Regulations on the Protection of Historic and Cultural Areas and Excellent Historical Buildings in Shanghai*. In 2005, it completed the protection planning of 12 historic and cultural Areas in the Central City and *the Planning for Landscape Protection Road in Historic and Cultural Areas in Central Shanghai*, as well as identified 144 landscape protection roads and streets (hereinafter referred to as landscape protection roads) in each historical and cultural area.

This paper attempts to start from two aspects: related planning control and actual protection situation of landscape protection roads, briefly combing the basic characteristics of Shanghai landscape protection planning

and trying to take Yuyuan Road (West Section) as an example to analyze its problems in related planning control and actual protection situation, in order to obtain and understand the highlights and problems in protection work of Shanghai landscape protection roads.

2. Brief Comment on the Planning and Management of Landscape Protection Roads in Shanghai

2.1 Overview of Management, Planning and Research of Lane Protection Road

The author sorted out the policy documents directly related to the style and features of roads : the *Opinions on the Planning and Management of the Style and Features Protection Roads (Streets) in Shanghai* (hereinafter referred to as "*Opinions*") which approved by the Shanghai Municipal Government in 2007 put forward the specific requirements including management mechanism, management requirements, planning basis and procedures, planning content, control elements and other aspects for landscape protection roads. This normative document would remain valid for nearly 10 years. In 2015, the Shanghai Municipal Government issued the notice of the *Municipal Government on Extension of the Validity Period of the Notice of the Municipal Planning Bureau Approving Some Opinions on the Planning and Management of the City's Landscape Protection Road (Street) by the Shanghai Municipal People's Government*, which clarified the guiding role of the "*Opinions*" extended to April 2020.

The planning related to landscape protect roads are as follows: ①the *Protection Planning of Historic and Cultural Areas*"(2005) for each area; ②the *Planning for Landscape Protection Road in Historic and Cultural Areas in Central Shanghai* (2005) approved by Shanghai Municipal People's Government; ③the *Planning for Landscape Protection Road* (after 2007) which some districts of the central city have already compiled. Among them, planning ① is the core of the landscape protection system, with the regulatory detailed planning as the carrier of the protection planning, and the main results are the planning text, instructions and drawings. Planning ② determines 144 landscape protection roads in 12 historic and cultural areas of the central city and carries out the overall planning and protection of "original flavor". 64 of them are classified as "*first-class protection roads*" and the other 80 as "*two-four-class protection roads*", which require detailed protection planning and strict protection of landscape protection roads. Planning ③ is a detailed and constructive planning for a particular landscape protection road under the guidance of the above two planning, which deepens and refines them. However, the project still remains in individual districts and hasn't cover all the landscapes and roads.

The research related to landscape protect roads are as follows: (Guo Jian, 2008) probes into the planning work of landscape roads, and analyses the difficulties, ideas, technical contents and interactive connection of management in landscape road protection planning combining with practice. (Hou BinChao, 2008) analyses the process of determining the road for the protection of Shanghai's scenery and the characteristics of the protection work and puts forward some suggestions on how to further promote the protection of historic street landscape and strengthen the function of public activity space on streets. (Sha Yongjie, 2009) takes Wukang Road as an example to study the history and protection planning of landscape protection roads and explore the protection planning mode at the level of constructive detailed planning combined with the protection comprehensive renovation project of Wukang Road. (Sha Yongjie ,Wu Jiang, 2013) studies the comprehensive protection planning of some streets of Hengshan Road-Fuxing Road historical and cultural landscape area in Xuhui District from 2011 to 2013, and probes into the deep problems of design management and implementation. Since then, Shanghai-style cultural writers have paid more attention to the style and road, describing the style and road in the form of literary works (Chen Danyan, 2014).

To sum up, the time of compiling and approving the planning, issuing the management documents and concentrating on the related research is 2005-2009. Since 2010, the implementation and management process of

the planning has been the main task. However, up to now, the normative documents have not been translated into laws and regulations, the protection planning has not been fully covered, and the related research is still less.

Figure2: Distribution map of landscape protection roads (streets) in central Shanghai (Source: Self-drawn by the author)

2.2 Main Characteristics of the Planning and Management of Landscape Protection Roads in Shanghai

2.2.1 Incorporation into the Heritage Protection System

The establishment and protection of 144 landscape protection roads have been incorporated into the planning and management system of Shanghai historic heritage protection in. The determination of landscape protection road has perfected the three-level urban historical heritage protection planning and management system established in Shanghai, which combines the key protection (excellent historical buildings) - street landscape protection (landscape protection road and street) - regional protection (historical and cultural area).

2.2.2 Classified management and clear focus

The historic backgrounds and the surrounding conditions of landscape protection roads are different, resulting in the different landscape situation. While 144 landscape protection roads have been identified, four-types landscape protection roads have been classified and corresponding protection and management requirements have been put forward. The environment of each scenic area in the central city is complex and the difference is significant. So, classifying 144 scenic roads and putting forward corresponding key requirements of protection and management is the basis for the long-term development of the work. They are very in line with the principles of classification of heritage protection.

2.2.3 Protection planning has limited coverage and its legal status needs to be upgraded

In the actual investigation process, the author found that although *the Opinion* has been published for more than 10 years, but so far most of the historic and culture areas have not carried out landscape protection road planning within. Taking Yuyuan Road historical and cultural area of as an example, its scope spans Changning and Jing'an districts, the section in Jing'an district has worked out *the detailed planning of North Maoming Road and Yuyuan Road in Jing'an District* for the eastern section of Yuyuan Road. However, the detailed protection planning of the section in Changning district has not been carried out so far.

2.2.4 Focus on top-down and neglect residents' participation

Street is closely related to people's life as a transportation and public activity space. The functional characteristics along the street and neighborhood communication mode are the source of vitality of the landscape protection roads. However, the protection of both regulatory and revision levels is based on the planning authorities, ignoring the use of residents around the landscape roads, and adopting a top-down planning model. Such practices often lead to the gradual replacement of residential functions and the relocation of aborigines, leading to high-end, personalized commercial stores and gradually separates from the consumption level of aborigines. The original life was replaced by a strong commercial atmosphere, the authenticity of history is left just with "empty shells".

1. Current situation of landscape road protection -- A case study of Yuyuan Road (West Section) landscape protection road

3.1 Research Objects

The historical and Cultural District of Yuyuan Road is one of the 12 historic and cultural areas in the central Shanghai, transforming from the residential area of the middle and high level citizens of ancient Shanghai. Though it has undergone a hundred years of vicissitudes (in 2018, held various commemorative activities of "Centennial Garden Road"), its residential function is still the main function and has the corresponding public service function. The historical and cultural area spans Changning and Jing'an districts. On the whole, Yuyuan Road and other historic protection roads are like the space skeleton, linking four cultural and conservation units and 46 excellent historical buildings.

The protection plan of Shanghai Yuyuan Road Historic and Cultural Area locates its protection goal as "restoring the original senior residence and matching landscape function of Yuyuan Road historic and cultural Area, strengthening the existing public service functions such as education and administration, and forming a relatively simple but closer to the overall function orientation of the historical prototype". The whole plan takes Yuyuan Road as the core carrier to build life functional spindle. In the historic and cultural areas has five identified landscape protection roads (see Tables 1 and 3 for details) and each road has corresponding protection requirements (see Table 2 for details).

Road name	Origin-destination	Planning road grade	Current Width (m)	Adjust the red line (meter)	Classification of Landscape Protection Road
Yuyuan Road	Changning Road-North Urumqi Road	Secondary trunk road	15.2	Maintain the original form	Third-type
Wuyi Road	Dingxi Road-Yan'an West Road	Access road	20	20	First-type
Zhenning Road	Xinzha Road-Yongyuan Road	Access road	12-15	20-24	Third-type
North Urumqi Road	North Urumqi Road-Yongyuan Road	Access road	12.2	18-24	Third-type
Wan Hang Du Road	Kaixuan Road-Hua yang Road	Access road	12	20	Fourth-type

Table1: List of roads protected in Yuyuan Road historic and cultural area (this paper takes Yuyuan

Road as an example) (Source: protection planning of Yuyuan road historic and cultural area,

translated by the author)

Classification of Landscape Protection Road	Features	Protection requirements			
		Road width	Building Protection along the road	Other protected objects	Control index
First-type	Protecting buildings and preserving historic buildings along roads are distributed centrally, and their features are obvious. The roads maintain historical width and basically maintain the original spatial scale.	No widening.	Strict protection of protecting and preserving historic buildings along the road. The general historic buildings whose scale and style are basically in harmony with the surrounding protection and preservation of historic buildings should also be mainly preserved, renovated and repaired.	Courtyard, greening, ancient and famous trees, distinctive wall, pavement, street furniture, street trees, etc.	Building height, volume, style, color, form, width, retreat distance, building spacing, etc.
Second-type	There are a certain number of protected buildings and historical buildings along the road, and a certain number of other buildings and development plots.	Generally, keep historical breadth and original scale.	Conservation buildings and historical buildings along the road a should be preserved.	—	Height, volume, style, form, width, distance and space should be coordinated with the surrounding historical buildings.
Third-type	There are a certain number of protective buildings and historical buildings along the road, but the proportion of protective buildings and historical buildings along the road or on one side is small.	It can be properly broadened according to the planning of the width of the red line, the protection of buildings along the street, the preservation of the location of historical buildings, street trees, greening and other factors.	A small number of protective and preservation historical buildings which are in contradiction with road widening can be treated by displacement, partial demolition and opening of arcade buildings according to building protection requirements. The ratio of height to width of planned streets should be close to the original proportion of streets.	—	Appropriate control of building height, style, scale, retrogression distance and spacing of development blocks along the road.
Fourth-type	The distribution of historic buildings along the road is less, but the road grid, scale and alignment of the	—	—	—	—

	road have certain characteristics.				
--	------------------------------------	--	--	--	--

Table2: List of classified protection requirements for Shanghai landscape protection roads (streets) (a case study of Yuyuan Road historical and cultural area) (Source: the author sorted out according to the *Yuyuan Road historic and cultural area protection plan*)

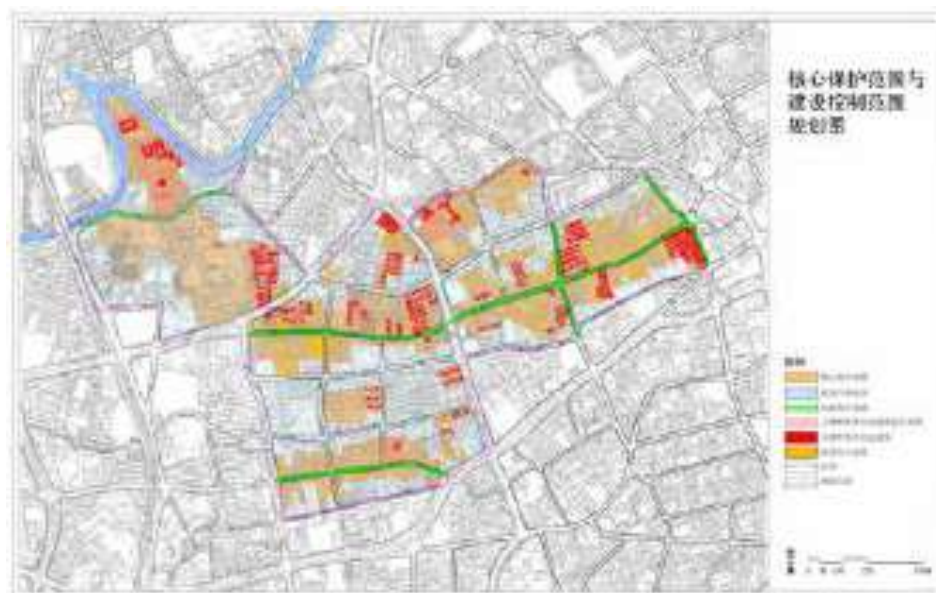

Figure3: Planning map of core protection scope and construction control scope of Yuyuan Road historical and cultural area (green one is landscape protection road) (Source: the *Yuyuan Road historic and cultural area protection plan*)

Yuyuan Road is divided into three sections according to administrative boundaries and roads: eastern, western and middle. The western section between Changning Road and Jiangsu Road belongs to Changning District with a total length of 0.91 km. Changning District has not formulated the landscape road protection plan at the level of constructive detailed planning for the western area. At present, the protection of Yuyuan Road landscape road (the western section) is mainly based on the historical and cultural area protection plan and *the Opinions*. According to *the Opinions*, the whole neighborhood section shouldn't carry out construction, repair and renovation activities due to the lack of protection planning for road.

The author makes a field investigation on Yuyuan Road (West Section) and the buildings along the street and tries to review the existing problems of the relevant protection planning through the analysis of its protection status.

The research area determined by the author is the envelope range of buildings along both sides of Yuyuan Road. The main section of the road is 15.2 meters wide, two-way lanes are about 9 meters wide, two sidewalks are 2.5 meters wide and plane trees are planted on both sides. Among them, there are 6 excellent historic buildings in Shanghai, and about half of them are protected buildings and historic buildings. In the whole length of the north-south interface of the street, the business interface accounts for about 61%, mainly clothing, banking and catering functions; the residential interface (including 17 entrances and exits) accounts for about 19%, mainly in the form of fencing; other public service interfaces (nursing homes, youth palaces, police stations, kindergartens) account for about 17%; other interfaces or those underdetermined functions due to the construction are about 3%.

implementation of the requirements of landscape protection, brings about the actual "*protective damage*" to the landscape.

Figure 6 Renovation details (1) (Source: Author's self-photography)

Figure 7 Renovation Details (2) (Source: Author's self-photography)

Figure 8 The landscape before the renovation of the street façade (Source: Baidu Street View Map)

Figure 9 Distribution of the same remediation method (green is the remediation point in the figure) (Source: Self-drawn by the author)

3.2.2 the disorderly refraction environment of street facades above the second floor reflects

insufficient guidance and participation of residents in protection

The main type of land used on both sides of Yuyuan Road is residential land. Therefore, in implementing the protection planning of landscape roads, some considerations have been made to achieve the balance between environmental improvement and meeting the needs of residents, such as setting up air-conditioning external hood for residential buildings from the second floor to above. But in the investigation, the author found that a large number of air conditioners were not hanging freely according to the requirements (Figure. 10). In addition, the disordered wire network, the additional drainage pipe and other problems also seriously damaged the street style, and even drilled holes in the wall to facilitate the access of lines (Figure. 11) and pipes. In the aspect of window updating, most users use silver aluminium alloy window frame to replace the original dark red grid window frame (Figure 12).

This reflects the problems of both residents and managers. On the one hand, it is not the residents that ignore the impact of these practices on quality and beauty, but they lack expertise and skills, platforms and mechanisms for communication and coordination in the process of updating and are unwilling to bear excessive expenditure to

maintain their appearance. On the other hand, managers often pay attention to the form of protection work in place, but usually neglect the supervision and guidance in the implementation process. For example, there is little tracing after setting up the shield, so that the residents who are lack of protection awareness destroy the appearance after installing the external aircraft.

In fact, the effect of indoctrinating the concept of protection to the residents is often far from expectation. A better way is to learn from France's experience in urban heritage and development of residential areas, and to encourage residents to fully participate in the work of landscape protection by using incentive policy of "carrot + stick" as incentive and punishment, so as to better "live regenerate" the historical heritage.

Figure. 11 Disturbed wires and pipes (Source: Author's self-photography)

Figure 12 Original dark red window frame (Source: Self-drawn by the author)

Figure 13 Silver Aluminum Alloy Window Frame (Source: Self-drawn by the author)

3.3.3 Random repetition of architectural renovation reflects the lack of relevant protection rules and irregular approval process

During the author's investigation, Yuyuan Road staged an aesthetic saliva war about the random and repeated facade modification. In pursuit of the concept of new fashion, a street art gallery employs overseas designers to transform the bottom facade of No. 1173 Yuyuan Road with flat black and white lines as the main elements (see Figure 15 for details). From the protection plan of Yuyuan Road, we can see that the building is classified as other buildings and the requirement of such buildings should be reconstructed or demolished, reconstructed or constructed in harmony with the features of historical and cultural area. The facade renovation of such buildings should be in harmony with the surrounding features.

Figure 14: The surrounding features of Fiu2 Art Museum (Source: Author's self-photography)

Figure 15: Fiu2 Art Museum after its facade renovation (Source: Sina Microblog)

Figure 16: Fiu2 Gallery Facade Restoration (Source: Author's self-photography)

It can be clearly seen that the facade style of the exhibition hall after renovation is obviously inconsistent with the surrounding features (compared with Figure 14), which seriously violates the planning requirements. Therefore, only a few days later, it will be required to rectify and restore its original appearance. The method of restoration is to use coatings to cover the newly modified coatings and complete the restoration in color. The head of the gallery declared that :“ The administrative procedures were complete and legitimate, and the streets and media were accepted. However, when an individual passed by accidentally, he would negate the effectiveness of the previous administrative procedures because he wanted to mobilize administrative power.” Regardless of their weak awareness of landscape protection in the transformation activities in the historic and cultural areas, if what they say is true, there are indeed irregularities in the process of examination and approval. The right of approval for the construction in the scenic area is in the competent planning department of Shanghai. Obviously, "street acceptance" doesn't have any effect on the transformation activities in the scenic area. The irregularity of the examination and approval process leads to the repetition and arbitrariness of building renovation, which should not be paid by the shopkeeper only.

Another problem reflected by the phenomenon is the lack of Yuyuan Road landscape protection planning mentioned above, and the delay in compiling relevant protection rules, which makes the competent authorities lack detailed and effective basis for approval. The details of judging "harmony" and "disharmony" of landscape and features should be further clarified in the protection planning. It is suggested that a "positive list" be established for coordinated transformation of style and features, and that objects such as pillars, doorways and steps be listed as elements that must be retained as they are, so as to materialize the unalterable objects and avoid repeated acts of destruction, such as those that are restored after the completion of the approved transformation scheme.

3.3.4 Priority of road capacity transformation reflects the difficulty of coordination among multi-authorities, which can not meet the deep-seated rehabilitation of neighbourhoods.

At present, according to the planning requirements, the width of Yuyuan Road (West Section) is maintained at 15.2 meters except for the widening of the roads at Jiangsu intersection and Dingxi intersection of Yuyuan Road at both ends. According to the location of the red line in the road system planning of the protection plan of the historic and cultural area, the intersection of Yuyuan Road in Jiangsu Province is widened reasonably. While the red line requirement of Dingxi intersection of Yuyuan Road in the planning is expressed as the one-sided widening of the north side (position ① in Figure 17). However, in the actual investigation, it is found that the traffic situation is complex due to the intersection of the three lines at the road intersection. In line with the principle of giving priority to road capacity, the ② section of the road is also widened. The non-motorized lanes are located outside the red line of the road, which violates the regulatory requirements in comparison with the planning.

Figure17: Red Line Map of Road Planning at Dingxi Intersection of Yuyuan Road (Source: the author draws his own picture according to the protection pla)

Figure18: reasonable broadening of ① (Source: Author's self-photography)

Figure19: irrational broaden of ② (Source: Author's self-photography)

Due to the particularity of both traffic functions of landscape characteristic, it is necessary to coordinate and balance the opinions of multiple authorities in the actual protection process. Municipal landscaping, environmental sanitation departments and transportation departments have played a certain role in the related work of renovating landscape roads, but they have different emphasis on the renovation work, and even conflict with each other. Irrational renovation behavior is prone to occur in the case of poor coordination and lax auditing. However, the protection of landscape roads has been incorporated into the heritage protection system. Regulations and repair regulations are the carriers of protection work and have legal effect. Any construction activities in scenic areas need to ensure the principle of "priority of protection" according to law. It is urgent to promote the renovation work led by planning departments and participated by many departments. Therefore, the planning and protection of landscape roads should be more comprehensive, and the protection of landscape roads should be taken as a grasp to promote the deep revival of neighborhoods.

4. Discussion on the Optimum Direction of Landscape Road Protection

4.1 Perfecting the compilation of protection planning and upholding the protection according to law

In terms of laws and regulations, it is necessary to speed up the incorporation of the requirements for road protection into the legal system and enhance the legal effectiveness of protection. In terms of planning, in the context of the increasingly detailed control system, the formulation of landscape road protection planning can be combined with urban design, giving full play to the flexibility and participation of urban design, and enhancing the rationality of decision-making. On the basis of improving protection planning, we should adhere to the principle of priority of protection according to law.

4.2 Cross-administrative cooperation and multi-sectoral consultation

Landscape protection roads are often not confined to a single administrative region. Due to the limitation of administrative boundaries, protection planning is divided into sections. The protection planning of landscape protection roads should carry out cross-regional cooperation and work out jointly so as to avoid the occurrence of different treatment situations. In addition, we should understand the particularity of landscape roads as historic heritage and solve street-related issues through multi-sectoral consultation.

4.3 Government guidance, residents involvement, making full use of flexible measures of market

The first problem found in the survey is due to unreasonable intervention by the competent authorities, while the second problem is due to inadequate intervention and inadequate guidance. The government should explore the flexible role of market mechanism in urban heritage protection under the condition of protecting public interests and strictly abiding by the bottom line of urban heritage protection and be a good rulemaker and supervisor. The government should neither dominate the implementation nor the neglect of destruction, transform the identity and establish a consultation platform instead so that willing residents and competent institutions can cooperate. May be PPP model is a good choice to achieve a win-win situation of style protection and quality improvement.

4.4 Promoting the concept of protection and drawing lessons from advanced international experience

By using advanced theories and methods such as "historic urban landscape" and making a more detailed study of historic and cultural landscape areas and road protection, protection planning based on research can be elaborated. It is important to combine the needs of protection and development to face the dynamic management of urban heritage. And drawing on the advanced protection experience of foreign countries to form a landscape road protection system with Shanghai characteristics.

Urban design for
multilevel planning

What role do urban policies play in enhancing the satisfaction from neighbourhood open spaces in mixed-use city centres: Lesson from Auckland

Salma Amirshakari Razno¹, Lee Beattie² and Cristian Alejandro Silva³

Abstract

Mixed-use neighbourhood and intensification have been widely identified as a positive urban strategy after research showed how this policy benefits the city and public, underpinning the concept of sustainability. In countries with well-established urban growth strategies, governments encourage people to settle in city centres as a mixed-use neighbourhood by considering new high-density residential development in this area. However, the design quality of these areas influences the residents' satisfaction within their neighbourhood. Providing quality open space is one of the main influencing factors of satisfaction however, spatial elements of these qualities are yet to be developed.

Auckland is the largest city of New Zealand and over the past 60 years, its City Centre has become increasingly populated and diverse (Auckland Council, 2012b). According to the Auckland Plan 2015, Auckland City centre will be one of the main residential centres of the city, and subject to this population increase (Auckland City Council, 2018). To cope with this demand, Auckland's urban documents such as Auckland Masterplan promotes a compact city with a high-density residential area which can be perceived as a neighbourhood by the residents. Therefore, regarding the main vision of Auckland Plan to be the most liveable city in the world, considering residents' needs and experiences, planning and designing open spaces is highly challenging.

This paper presents the approaches to the open space in Auckland City Centre. The central question of this research is how residents' viewpoints are coordinated with the relevant urban documents. To answer this question, content analysis of the main and relevant urban documents have been conducted. This research raises the issue of urban policies and the role this plays in the residents' satisfaction with their neighbourhood open spaces.

1- City Centres are a neighbourhood under the growth management plan

The growth management approach is coming back to the city and looking at the city centre not just as a commercial zone. Review of the city plans under the growth management programs shows how city centres are seen as a neighbourhood and how they are prepared for having more residence in this area. While providing quality urban open spaces to meet

¹ School of Architecture and Planning, University of Auckland, Auckland, New Zealand

² School of Architecture and Planning, University of Auckland, Auckland, New Zealand

³ School of Architecture and Planning, University of Auckland, Auckland, New Zealand

the resident's demands is one of the main plans of some of these report, neglecting these elements of neighbourhood satisfaction can be seen in others.

For example, a report published by City of Toronto (2014) entitled "Trends, Issues, Intensification, Downtown Toronto" explains that recent population trends, where residents are looking to live in city centres at increasingly diverse life stages, has resulted in the need for new brownfield developments to prioritise a dynamic mix of housing and workplace types. In 2013, City staff and consultants of Toronto undertook an extensive consultation process with residents of condominium buildings across the city. The feedback from the residents showed that "there was a clear overall impression that services and infrastructure were not keeping up with development, and there was a need to better coordinate development with the requisite infrastructure and services". One of the comments shows that there are more demands for proving places for people (and dogs) in the public realm – parks, open spaces, sidewalks, etc. The report also shows how the design of downtown Toronto is influenced by feedback from the residents(City of Toronto, 2014). A report of this nature couldn't be found for Auckland.

Vancouver is another example from Canada that has a mixed-use downtown. According to the Vancouver Council website, Places for People Downtown is a planning project that started in summer 2017. They "launched a summer engagement campaign and an online survey to better understand the public's thoughts and attitudes toward public space in Downtown Vancouver" to achieve a well-designed downtown for the general public (City of Vancouver, 2018). This emphasizes what a topical and timely piece of research this work could be for Auckland.

Centre.City.Plan (2007) is the plan for the Calgary downtown in Canada. This report explains how a shift has occurred in Calgary towards having a more livable city during both day and night times. The report explains that "The liveability of the Downtown should be reinforced by supporting residential developments and associated amenities that will generate day and night activity" (p.36). The Plan has policies to support the refurbishment of older existing buildings and the integration of new residential and mixed-use developments because it is considered that this approach results in high-quality public realm outcomes (Land Use Planning and Policy-Planning, 2008).

Plan Melbourne 2017-2050 also shows that the City of Melbourne is looking at the development of its city centre as a good area for providing more housing choice for residents. One of the key goals of the plan is to provide "housing choice in locations close to jobs and services" (p.9). One of the main strategies to achieve this goal is to "facilitate well-designed, high-density residential developments that support a vibrant public realm in Melbourne's central city" (p. 9; Victoria State Government, 2017). This Plan lacks detail about how this can be achieved and in this way is relatable to Auckland where this type of implementation information is lacking.

Sydney is another example from Australia. 'Sustainable Sydney 2030' has ten strategic directions. "Housing for a diverse population" is one of the ten directions and explains the priority of having more diverse residents in central Sydney (City of Sydney, 2008). Again, explanations of how this can happen and the role of open spaces are at times lacking from the strategy document.

2-2- Importance of considering subjective design quality of neighbourhood open spaces for making a liveable city

In a similar vein to the mentioned examples, the growth management approach in Auckland's city centre as a commercial zone has shifted towards a focus on delivering a liveable downtown neighbourhood. New community associations have been established to focus on this process (such as Splice community group and Auckland City Centre Residents' Group – CCRG) and talking about the quality of life of residents living in the city centre has become an increasing research priority in Auckland (Carroll, Witten, Kearns, & Donovan, 2015)

Over the past 60 years, Auckland City Centre has become increasingly populated and diverse (Auckland Council, 2012b). During 2015, more than 5000 people moved to Auckland City Centre with approximately 34,000 people now living in this area (Tapaleao, 2016), having been drawn by its location, ease of access to amenities and affordable houses (Auckland City Council, 2015). To cope with this demand, the Auckland's plans such as Auckland Masterplan promotes a compact city with a higher density residential area (Auckland City Council, 2016; Auckland Council, 2012b; Auckland Regional Growth, 1999). However, the compact city paradigm could be a threat to the existence of open spaces. More research is needed into how open spaces in downtown neighbourhoods function and can continue to be prioritized as intensification remains ongoing.

Auckland council desires to make Auckland the most liveable city in the world (Auckland Council, 2012a) while Satu and Chiu (2017) by reviewing the literature show how the concept liveability is defined by the experience and evaluation of community from their living environment. Therefore, the experience of residents of Auckland City Centre is really important to achieve the main goal of Auckland Council to be liveable. Liveability is a multidimensional concept which the geographical aspect of this concept is known as the urban quality of life (Satu & Chiu, 2017). There are two main streams of research in the study of quality of urban life, including objective (a measurement which considers the actual situation and numbers) and subjective (a measurement which considers satisfactions). Various scales have been seen in the quality of urban life studies including region, a city as a whole, neighbourhood and dwelling (Marans, 2015). Therefore, Satisfaction with the neighbourhood as a socio-spatial unit (Allen, 2016; R. Chaskin, 1997; Sharifi, 2016) can improve the quality of life of residents.

Many factors can influence neighbourhood satisfaction, and these factors have been seen in urban and another field of studies. The neighbourhood is a socio-spatial concept (R. J. Chaskin, 1997) and neighbourhood public open spaces are one of the urban design elements influence

chance of neighbourliness as one of the main factors of subjective quality of urban life, well-being and neighbourhood satisfaction in neighbourhood context (Grannis, 2009). This urban element has been seen in physical factors that affect the neighbourhood satisfaction although some time in different form such as naturalness, openness and green area (Ferreira, 2016; Leslie & Cerin, 2008), (natural) open space (Amérigo & Aragones, 1997; Mohit, Ibrahim, & Rashid, 2010; Yang, 2008), public space (Mee, 2010; Yang, 2008), recreational space (Addae-Dapaah, 2008; Mee, 2010), outdoor park (Florida, Mellander, & Stolarick, 2011), urban space, or shared public space (Yang, 2008). However, open space contains three main aspects including perceived, conceived and lived space (Lefebvre, 1991). Therefore this research is focused on the experience and evaluation of open space in the scale of the neighbourhood as an effective factor that influences liveability and quality of urban life. Knowing users experiences are really important in urban design and planning as although it can depend on psychological situation of users, structural situation is also involved in the perception process (Bratina, 1997).

2-3- Urban policies, urban documents and the missing place of objective factors in Auckland urban documents

Achieving high-quality design is the main goal of urban policies and documents. However, it seems that the role of these disciplines has not been considered enough in neighbourhood satisfaction area, especially related to achieving design quality in neighbourhood open spaces. Carmona (2014) argues that urban design should have a holistic approach to all activities that influence the outcomes and place. He argues that “urban design projects are rarely subjected to a post-occupy review in the way that buildings are, and almost never is a systematic view taken across the entire process of creating or recreating places” (p. 4). Madanipour (2006), advocates the multi-dimensional perspective that needs to be considered during the design process which is not just focused on the single area. This dynamic approach let us record the individual voices, besides considering the context to propose more practical conclusion.

Auckland is the biggest and the fastest growing city in New Zealand with 1.66 million population (Stats NZ Tatauranga Aotearoa, 2017). Over the past 60 years, Auckland City Centre has become increasingly populated and diverse (Auckland Council, 2012b). Auckland City Centre Masterplan (2012) the population of residents in Auckland city centre will grow from around 27000 people in 2012 to 45000 people in 2032 while the statistic shows that the population growth exceeds this prediction in 2017 (OurAuckland, 2017). The location, ease of access to amenities and affordable houses are the main reason for choosing this area (Auckland Council, 2015a).

Figure 1. The location of Auckland City Centre (Google map, 2019)

Mixed used city centre has become a desirable strategy after research shows how this policy can benefit city and public regarding social, economic and environmental (J. Grant, 2002; J. L. Grant & Gregory, 2016; Jacobs, 1961; Talen & Koschinsky, 2014). This strategy leads to downtown residential development and increasing settled residents in city centres. In the same vein, Auckland City Centre Masterplan (2012) recognised this urban area as the Auckland city centre instead of CBD, to make a place to live, work and play (Auckland Council, 2012b, 2016a; Auckland Regional Council, 1999a). This area has been defined by the motorways and the coastline (Figure 1ure) which followed by the present research the initial boundary. Therefore, Auckland Masterplan promotes a compact city with a higher density residential area (Auckland Council, 2012b, 2016a; Auckland Regional Growth, 1999) which makes this area distinctive from other parts of Auckland.

While the compact urban forms need more urban design consideration to keep the residents' satisfaction within their living areas (Hur, Nasar, & Chun, 2010; Kearney, 2006; Mouratidis, 2017), more tendency toward the suburbanisation policies in Auckland, led to decline the spatial condition of Auckland City Centre (McArthur, 2017).

In this research archival research is conducted to review the legislative and governmental policies related to open spaces in Auckland, especially Auckland City Centre. This data is in form of text and, web-based, available online in Auckland Council's website limited from the initial plans related to these space from 2012 to 2016 (almost the time that the research has been started). Choosing these documents were the result of consulting with experts and engaged people in the process of urban design in Auckland. The reports include:

- The Auckland Unitary Plan (2016)
- City Centre Masterplan (2012)

- Parks and Open Spaces Strategic Action Plan (2013)
- Open Space Provision Policy (2016).

All of the above documents were available free for the public on the Auckland Council web page and can be seen in two parts including statutory and non-statutory documents. Currently, the only statutory documents relevant to the open spaces in Auckland in Auckland Unitary Plan (OP) (2016). Open Space Provision Policy, which is non-statutory document has been eliminated from the research, as it has mentioned that the “open space provision in the city centre is primarily guided by the City Centre Masterplan.” (P.38).

The Auckland Unitary Plan

The Auckland Unitary plan operative is launched in 2016 which follows the national goals and plans of New Zealand and will guide Auckland's future over the next 30 years. Auckland Unitary Plan can be seen in both scales of the regional and urban plan as it has shown where, what can be constructed in the Auckland region. The plan is underpinned by a zoning system and defined in fourteen chapters. In chapter H, relevant to zones, H7, is about the open spaces which explain the possible activities in open spaces considering the environmental conditions. Overall, Auckland Unitary Plan has more concern about the height of the building and their visual effect on the special characteristic area of the city centre. While it is not very clear about the quality of the apartments. However, sometimes it is mentioned that the quality of these places is important and it is important to make clear the boundaries of public, semi-public and private space. But obviously, it does not explain how this (design) quality can be providing and how the plan involves in encouraging the developer to consider this quality in the design.

Auckland Unitary Plan encourages more residential development in the city centre especially for providing passive surveillance at night. However, chapter relevant to this part of the city named “H8 Business- City Centre Zone” which is not in line with the mixed-use nature of the area. Furthermore, the quality of these land use and type of development are not granted for residential development. The only rule which should be relevant to provide the neighbouring space for residents is the bonus floor area policy. This rule started on And it is not too many researches about the efficiency of these space. However, research by Dempsey and students at the University of Auckland shows that most of these spaces are not opened or welcoming for public and does not benefit them. While it also increases the price of buildings considering providing nice building lobbies.

Chapter I, in Auckland Unitary Plan is also about the special locations where their own special rules must be followed. I203 is about the City Centre residential Precinct that identified four residential precincts in Auckland City Centre including Emily Place, Whitakere Place, Myers Park and Scotia Place. It explains that for having a good standard of residential amenities, the Auckland Unitary Plan is going to provide more quiet spaces with good access to the amenities in these four mentioned areas.

Auckland Unitary Plan is more clear and strict about residential development in other zones. For example, in most of the residential zones it is clear that the developer needs to provide some outdoor spaces while it is not compulsory for residential development in the city centre.

City Centre Masterplan (2012)

Auckland City Centre Masterplan is a place-based plan that released in 2012 with the aim of making the Auckland City Centre more appropriate and safer for family, pedestrian and environment. This plan will guide Auckland's city centre future over the next 30 years. Value of the open space is one of the ten vision of the plan. However, there are other visions that could be relevant to open spaces such as public life. The plan has been reflecting the defined vision in eight different areas in city centre. There are most focused on connectivity and making some safe spaces by decreasing the number of cars and adding a new light rail in the city centre. The plan has been defined in three episodes including 2012-2022, 2020-2032 and 2025-2042. Therefore, it is very soon to assess the success of the plan. However, what can be seen is that, while Auckland City Centre masterplan predicted 45,000 residents in the city centre by 2032, the new statistics show that the number of residents living in this area has already (2018) exceed. Furthermore, being more details, the residents are not directly involved in the decision making process and design of any areas as they are eliminated from the mentioned partners of the plan.

Parks and Open Spaces Strategic Action Plan (2013)

This plan aims to show what needs to be done for park and open space networks in Auckland city Centre for future 10 years and follow the Auckland Plan. Like Auckland Plan, the park and open spaces are defined in seven groups including Hauraki Gulf Marine Park, regional Parks, Wild and remote places, natural Area, benched, volcanic cones, local parks and civic spaces. As can be seen, the definition is showing that the plan is more focused on natural open spaces and the urban open spaces are limited to civic spaces and local parks. By looking at the definition, it seems that the open spaces in city centre are just limited to civic spaces. Civic spaces include civic squares, town centres and stress and the plan mentioned that these spaces are usually forgotten while they improve connection and linkage. Therefore, considering the definition, these are not spaces for sitting and spending time.

As such the other policy documents, it seems that Auckland City centre is not included in these documents. While it seems that the policies have not been developed enough in a practical way and it is not clear how the “open space network” will be identified and developed through the urban and regional area. In summary, this plan can be seen as a political plan. Therefore, the lack of a place-based plan can be seen.

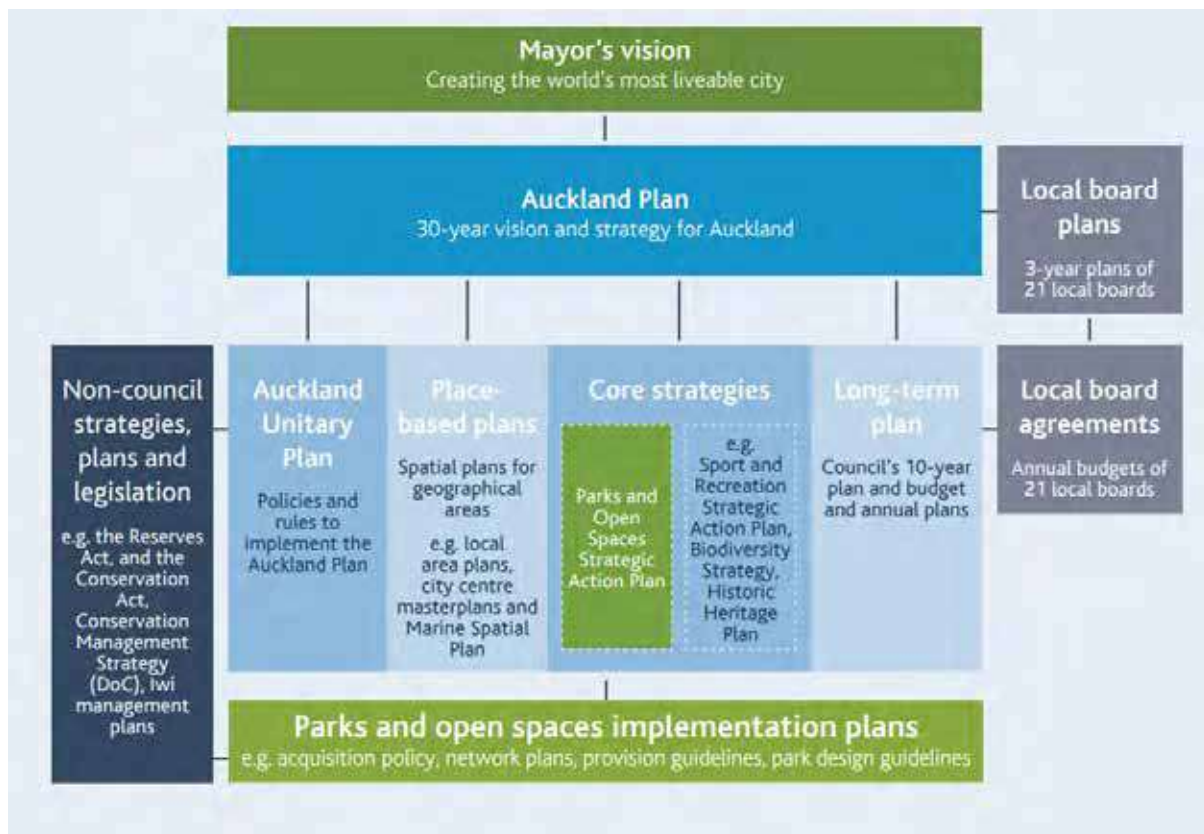

Figure 2. Relationship between the Parks and Open Spaces Strategic Action Plan and other strategies (Auckland Council, 2013)(P.13)

Discussion

This paper aims to show how urban policy influences neighbourhood satisfaction through the design outcomes. Auckland Council gave attention to the open spaces especially recently. However, most of the urban tools are in policy level and focused on the natural open spaces (which are different from urban and neighbourhood spaces).

In the case of Auckland City Centre, the area is more sensitive comparing another part of the city to urban open spaces planning as the values of the land is higher. Commercial developments and market's power try to shape the form of the city in this area and eventually influence the amount and quality of open spaces. This issue can change the experience of the residents from their living environment.

Although research has been done by Auckland Council to improve the physical design of urban open space (Auckland Council, 2013, 2015b, 2016b), they usually have considered the top-down approach to the open space planning strategies as it has not been seen in the statutory documents. These urban documents have not conduct subjective studies about how current users experience these spaces. However, recent research has indicated that existing open spaces do not meet the needs of inner-city residents(He, 2015; Splice, 2016). This issue leads to a number of problems for residents, including social isolation (Carroll, Witten, & Kearns, 2011; Chile & Black, 2015; Owen, 2016).

Additionally, the result of the survey has been done in Auckland City Centre shows that the most concern of residents living in Auckland city centre is their involvement in the design and maintenance of open spaces in their neighbourhood (A. Razno, 2019). However, looking at the policies shows that, while always engaging people was the main concern of the policymakers, as the design of the open spaces is completely depends on the developer, these engagements are not always possible.

It is possible to argue that, despite policy attempts at developing liveable open spaces, issue in urban spaces emerge as an outcome of less-controlled processes in planning occurring as a series of policy absences and ambiguities. Additionally, while there were recently some urban design projects such as Lord Freyberg in Auckland City Centre that has been designed by involving children in the process that has been done by Massey University and Auckland Council in 2017, it seems that for having more liveable city, which is the main goal of Auckland Plan, stricter and clearer urban documents need to be provided. Recognizing the role of urban design and residents, and involving them in the project relevant to open spaces, is something that directly influences the outcomes and quality of the spaces. More research needs to be done to find out the tools that can be used to encourage more public involvement in urban project in Auckland.

Opportunities, innovation, and legitimacy in Public-Private Collaboration. Lessons from French practices

Camilla Ariani¹, Giacinto Donvito²

²*La Sapienza - Università di Roma - School of Planning, giacinto.donvito@uniroma1.it*

Abstract: The debate about urban regeneration is coping with the spreading of public-private interactions and new geographies of powers. Thanks to a lexical shift from Public-Private Partnership to Public-Private Collaboration (PPC), the research aims to investigate these approaches to urban transformations and, analyzing the features of French best practices, outlines innovation's potential of such experiences. Four cases were studied as an advanced form of PPC for city-making, with widely recognized high-quality outcomes. The shift to PPC opens to a discussion on multilevel planning, in order to find a balance between reduction of public finance, need of urban renewal for collective services and public spaces, role of private stakeholders; collaborative urban transformations deal with privatization and regeneration, gentrification and inclusive social transformations, (neo)liberal city and public city. In this work, practices' features are translated into clusters of indicators to deconstruct the complexity of urban quality. Through the checklist and the following evaluation process, PPCs in urban regeneration can be enhanced through the link between decision-making processes and the urban quality of the outcomes. The whole work aims to obtain practical guidelines for urban planning and design, providing insights for policymakers and urban design practitioners to define performance metrics for PPC.

Keywords: Public-Private Collaboration, Urban regeneration, Urban Quality, France.

Introduction

The socio-economic, political, institutional and normative changes that shaped most of the European cities in the last 30-40 years produced the insurgence of new relationships between public decision-makers and private stakeholders, new geographies of power that influenced the approach to projects and practices of urban transformation. These relationships developed within an idea of state and public action that has been changing through the years. Namely, following the 2007/2008 financial crisis and the increasing welfare state and democratic representation crisis, the development of these new forms of interaction pointed out the need for a deep reconsideration in urban transformations' governance, mostly about the outcomes of public-private actions on the cities, both from a spatial and a social point of view.

Forms of interaction among public and private players, usually defined as Public-Private Partnerships (PPP), were, at first, conceived to implement specific types of operations, mainly infrastructures or facilities (Sagalyn 2011, EC 2004). Gradually, PPP tools have been used in various fields, not always in a proper way. In fact, these tools very often revealed to be unfitted for urban regeneration or (re)development; it has proven to be more difficult to intervene in existing cities, because of the complexity of land ownership and land value, layered urban fabric and functions, uses and symbols.

With these premises, many cases of urban regeneration PPP could be labeled as a failure, because of flaws in public-private interaction, or lack of long-term planning; all conditions strengthened by the scarcity of public and private resources in the aftermath of the crisis. But still, there are some practices strongly innovative in the dynamics underpinned a variety of different players and movers; most of PPPs advocates point out the

efficiency of PPPs even with their demanding and complex strategies; in these approaches could be found the innovation key to build a new paradigm in urban transformation and (re)development.

Talking about actions on the consolidated city, the complexity of urban transformation drove us into an investigation on correlation between decision making and actual outcomes, on balance between public and private stakeholders, and on the definition of public interest and output's quality, beyond financial and economic evaluations. But regeneration and redevelopment are now an uncertain field for PPP. It is easy to use PPPs to build and manage projects that guarantee an economic return for the operation (as toll infrastructures or services provision and facilities), while it is difficult to design public-private procedures for projects without a clear economic return, where the public interest plays a major role, and the private investors are involved with a bigger degree of risks. It could happen that public decision-makers settle down to compromises in order to attract private stakeholders. Therefore, the risk is to implement market-driven strategies, losing the potential of innovation of complex and multifaceted project approach.

These are the starting points for this work, aiming to define suitable innovations to improve and strengthen the opportunities within the public-private relationship in order to obtain more quality in urban transformation processes. The research question can be expressed as followed: which public-private processes toward urban transformation of the consolidated city produces the best performance in terms of outcomes' urban quality, with specific attention to spatial outputs and effects on the public realm?

In this paper we discuss the potential of a different approach to the study of Public Private (re)development as a different pace for intervention on the existing city, to build a more just and equal city. We suggest a lexical shift to go beyond the ideological bias that marked the reflection on PPP in the past. Then, we present a reflection on urban quality and how it could be framed and evaluated. The rest of this paper focuses on the lessons learned from four French cases studied. We presented the use of indicators useful to highlight patterns for effectiveness and quality. The conclusions set a series of principles to be followed to achieve good performances and quality in urban transformation on the existing cities.

The need for a lexical shift

It was crucial to identify an alternative approach to the common form of public-private relationship, by exploring new definitions of the issue as Public-Private Collaboration (PPC). Market and planning, public and private, have been seen as faces of the dualism that characterizes urban studies. Since the 80's, the ideological, political and economic background has deeply changed. The term Public-Private Partnership referred to operational agreements to implement infrastructures, facilities, and urban transformation; transactional model spread in parallel with the rise of neo-liberalism: in literature and, afterward, in public debate, language and ideologies overlapped.

Theoretically, and etymologically, choosing the term *partnership* could refer to a large family of tools and different approaches; but through the years, the word gained a non-neutral meaning and interpretation, connected with public-private dichotomy (Linder, 1999). The dynamics between public and private are investigated as if, when one of the sides gains ground, the other one is supposed to lose (and this interpretation is sustained both from PPP's advocates and their opponents). Speculative discussion on this topic can be interpreted in two ways: on the one side, the ideologization of the analysis connected with the debate on neoliberal city (Le Galès, 1995; Sagalyn, 2011, Swyngedouw Moulaert Rodriguez, 2002, Mirafteb2004); on the other side, the distress in analyzing rigorously processes that are heavily influenced by social and institutional environment. Beyond that, there is a group of studies that consider the PPP as a kind of cure-all procedure, useful to deliver infrastructures, services and urban transformation in a post-crisis and post-ideological world (Hodge, Greve & Boardman 2010.) In the various national frameworks, terminology and taxonomy mirror

specific approaches to theory and practices. There are several terms used for these dynamics, each one is an expression of different meaning and interpretations.

In this work, it was necessary to adopt a language that allows a holistic approach to practices' analysis, beyond the ambiguity. A term to balance neutrality (to go over ideologies) and a broader look at an in-depth investigation on urban transformations, as a complex issue; for this reason, we suggest to use the term *Public-Private Collaboration*.

Usually, a collaborative process is intended as a network interaction, hence, out of a strong hierarchy; in other cases, the adjective refers to the development of bottom-up practices: in informatics or in the new economy, collaborative networks are peer-to-peer networks or open-source software. Nevertheless, the term "collaboration" is used in urban studies too, with diverse meaning following the interpretation of decision-making patterns. Patsy Healey, with her seminal book *Collaborative Planning* (1997), talks about planning as an interactive process, an activity derived by governance and interaction within a players' network. Her strategic spatial planning is an alternative to the mainstream 80's theories, in which strong importance of economics and market-led theory contributed to broaden inequalities, and urban regeneration was above all focused on attracting investors and money; therefore quality was an output of private investment rather than a goal of urban policies. Strongly rooted in the study of power balance, social interactions, and communication, Healey define the research on Collaborative Planning as a comprehensive thought on the role of communities, and therefore relations, in improving social economic and environmental policies at a regional scale.. It's important to study power relationship, global economic changes of paradigm, institutional design and so on, but at the same time to search for a way to give tools to the practitioners about how to act and manage complex transformations. Hence, *collaborative* is referred to the integration between strategies in planning and spatial dimensions of urban policies. In the introduction, Haley states that "(...) planning systems and practices, (...) have their power and justification in the role they play in helping the political communities of places work out how to manage their collective concerns about the qualities of shared spaces and local environments(...)." (pages 3-4, 1997). Bovaird (2004) uses the term *collaborative* referred to the interaction between public and private: Collaborative Partnership is the best form of PPP in order to solve complex issues through good governance and beyond business agreements. Collaborative partnerships are based on participation, transparency and communication with all the stakeholders in order to create trust, accountability, equity, social inclusion, fairness and ethics, just and innovative procedures to enhance the performances, competitive fairness, leadership and coordination.

In our research, *collaboration* is meant as a sharing of knowledge and expertise, with a focus on communication, accountability, and transparency within the players' network. Collaboration is about agreements between players that couldn't be able to implement processes, projects and urban transformations by themselves. Collaboration is on a different level from competition and concurrence (as ideas strongly connected with market logic, and commonly associated with PPP). Actions and interests can define synergies that produce a different outcome from the simple sum of actions and competences. When we talk about PPP it's important to understand who makes what in the urban development, what kind of gain and how everyone can pursue their own goals (no matter how the goals are defined). When we talk about *Public-Private Collaboration*, instead, it's important to understand who decides and defines the goals, what kind of interest it's at stake, and through which synergy (how the interests and the goals are defined, by whom) while looking at the broader outcomes following the accomplishments of said goals in the mid- and long-term.

Namely, Public-Private Collaboration is about the relationship among a network of stakeholders built upon integrated complex processes with the effects both on the physical transformation of the city and on the socio-economic issues, with the proposition of a model of development and growth that connect redistribution with market logic. Subsequently, examples in urban transformation with this focus can be defined as "collaborative urban transformation". Hereby, we are not suggesting the development of a new taxonomy of planning and

development tools, opposite to PPP; the aim is to suggest a different interpretation, beyond ambiguity but with complexity. *Public-Private Collaboration* defines an approach to public-private relationship and comprehends various kinds of tools, PPPs too.

Issues in the definition of urban quality, a choice of useful indicators

Defining guidelines to improve PPC needs the establishment of performance metrics that investigate the complexity of the issues and take into account the legitimacy of such public-private interaction. One important aspect is the evaluation of the outcomes, and therefore the definition of urban quality. Another important aspect is the accountability of the players involved, through the search for the public interest. We tried to connect these two issues. The definition of what is public interest it's at the core of the definition of urban quality. Public interest, or better "general interest", is the conjunction of multiple different interests, not always in opposition.

But urban quality is more an evocative idea than a descriptive and normative definition. It is important to pinpoint urban quality's features that could link outcomes with upstream urban transformations' processes. As we have defined PPCs as tools to overcome complex problems, the evaluation criteria can't be framed only in efficiency or partners' ability to accomplish tasks and to follow agreements. This means that PPCs need to be focused on better quality of life, and therefore urban quality, for citizens and city users (Bovaird, 2004).

The legitimacy of decision making is an overarching issue and crucial theme, in order to define quality: we needed to build a shared theoretical framework, through diagnostics of the problems to whom the transformation and planning, either strategic or not, would answer, through adaptability, resiliency and multifaceted approach. Outcomes of urban transformations are or should be, the answer to what has been defined as a public issue, paying attention to citizens' needs and demands. The creation of new urban qualities in the existing city is the main feature that marks complex urban transformations, which are no more aimed only at growth but at adding values to resources already contained into existing cities. This demanded improvement follows five Lynch criteria along with the two meta-criteria of efficiency and justice. The interaction of five dimensions, vitality, sense, fit, access, and control, with the overarching framing into the meta-criteria, puts the oversight of procedures and practices on the spot in the study of the relationship between processes and outcomes. Given the complexity and diversity of urban projects, the main design framework is based upon public spaces and public facilities that shape every single project within the bigger strategy.

The importance of public space quality in urban production originates from the specific idea of society and of what livability is in the city. Livability and urban quality are values that need to be shared by communities and groups as an expression of the particular cultural and theoretical framework. There is not just one answer to the search for quality, and it is no easy to find a working approach, without creating a conflict arena, as different communities could have unmatching issues. Trying to define what urban quality is could be a wicked problem, and sometimes the pursuit of urban quality creates more problems. With our framing, we can say that urban quality is the ability to answer to territory and community concerns. When an evaluation method is used to explain and legitimate decision maker, evaluation allows defining what public interest is and communicating to citizens, users and constituency.

This overarching search for a wider definition of urban quality is part of the evaluation of PPC outcomes outside economic efficiency and competitiveness. A multifaceted approach and specific focus on public realm have been used to define and shape the goals of collaborative transformation, highlighting the correlation with variable and parameters of decision making and network building as framed in the lexical shift to Public-Private Collaboration. As urban quality, general interest is not an absolute value but is related to framework and diagnostic of the urban issues. Not underestimating the complexity of the issue, we built the research process in order to find a clear and working method to evaluate the performances and analyze the added value to the redeveloped city toward a better quality of life in the urban spaces. We used the case study to define

characteristics and problems within different procedures, in order to draw a system of comparable variables; features in urban production that allow reading the urban transformations in relation to the added value of PPC.

Thanks to the cross reading of variables and outcomes, it was possible to define patterns that link process' quality and outcomes' quality. Said relationship with a focus on players interaction, allowed to read the outcomes as dependent variables connected with collaborative processes. Usually, evaluation protocols for complex processes are multi-criteria matrixes that need a huge variety of parameters and indicators that are not always easily applied. Therefore we have defined a simplified set of variables in order to be used also to define ex-ante the conditions needed to improve actions and the prerequisites to attain good quality in the outcomes.

In the first cluster, about *independent variable* within the process, the value scale from 0 to 10 is defined so that higher values coincide with a higher synergy among the actors and bigger consideration of general interests. A particular specimen is in the parameters related to the risk allocation, in which the balance between values matches with a higher synergy.

The six variables could be articulate in further sub-parameters, in order to better describe features needed to highlight development patterns. The main thesis is that these areas of interest should be taken into a bigger account if we want to build effective collaborative processes and quality in urban transformations.

Time framing and duration: time framing is an element that defines the structure of the project. It is articulated in two different values. Flexibility, about the inner characteristic of the project, and the capacity to evolve and improve as the time goes by. The strategic frame instead is about the links between the projects with a bigger picture, timewise and space wise.

Responsibility and public oversight: about the role of public agency in the definition of general goals, as a subject that guarantees broader protection of public interest.

Selection of players and their role: Player network is analyzed in two aspects. Selection of private players is useful to analyze the role of economic factors and quantitative evaluation in the building of players' network. Negotiation and participation are about the role of other players and stakeholders, such as citizens or civil society in the players' network and building of a strategic frame.

Land management: The use and ownership of land can follow merely financial issues and bargain logics or can be used as a tool to involve a complex network of players and complex management of the project.

Risks allocation: that is a peculiar item where the balance in the values usually describes a higher synergy. In order to describe better balance, we separated private risks from public risks.

Control and coordination: the capacity of oversight agency to use available tools to manage and control each operation and project.

In the outcomes cluster, named *Forms and outputs*, urban quality is defined through simple items, in order to easily define the quality of each aspect. In this set too, we used a scale from 0 to 10, where the bigger value describes the higher quality of the outcomes. The results of the urban redevelopment are described through six items, a checklist that allows to easily evaluate them.

Goals-outcomes consistency: it concerns a more complex evaluation, connecting the overall outcomes with the goals set at the beginning of the urban transformation decision-making and process. The evaluation paid particular attention to the outputs in the public sphere.

Public space: this is both a qualitative and quantitative evaluation, dimension and role in the general strategy of the project are evaluated.

Accessibility and mobility: in this case, it is important the enhancement of infrastructural services thanks to the project implementation.

Urban fabric and architectural quality: This indicator analyzes mainly the urban form and it is organized in four different parts. Density is about the operation as a whole, and it's strictly connected with the dimension of public space. Urban design quality it is connected with the neighborhood identity and image, and innovation in urban fabrics. Similarly, architectural diversity and quality measure the experimentations and search for technical innovation in every intervention.

Facilities, urban function and neighborhood's identity: the subdivision of this point is functional to identify the usage value of the new neighborhood with a focus on mix of use, housing stock, and supply of public services and facilities at the local or metropolitan scale.

Externalities and other outcomes: the project is evaluated in relation to the urban environment in which is framed. We analyzed the connection with surrounding urban fabric (therefore on a spatial and local basis). On the other side, we highlighted the overall effect on the city on a general basis.

A short overview of practices

France experienced practices on complex urban transformations since post World War II, shaping a network of players, institutions, roles, and expertise in a constant evolution of decision making and implementation processes. Since the '70s, *Projet Urbain à la française* is a term that describes a well-established approach to urban redevelopment: there was a significant shift from the construction of new public housing (even with the demolition of ancient neighborhoods) to interventions on the existing city, in order to update urban fabric and give back to the citizens under-used parts of the city, because of de-industrialization. French planning tradition is based on regional economic planning, a collaborative and integrated approach; it became more and more important during the devolution process, with its new institutional governance delegated to local administration, therefore with a change in public agency scale. Even considering this change (influenced by EU policies) public power maintains decision making control to oversight and defines the space for the private players. Also, it shows that giving importance to economics in urban transformation doesn't always mean letting too much space to financialization in urban dynamics.

On these bases we have chosen to study cases with an interesting players' interaction, defining a triangular relationship among practitioner (planner, architects, and experts), developer and public agencies. It's the network that drives real estate developments, and it works easily in thriving markets while it struggles in recession cycles. We have chosen the implemented projects, in order to analyze and evaluate the outcomes of the studied processes. We investigated players' role, public movers (central or local agencies, other public or social players) and private investors (developer, construction firms, funders) in order to point out connections and interdependence between the type of collaboration, players' role, outcomes, and output.

In this work we are shortly presenting the main features of the four cases¹. The diversity of the cases was important to generalize the highlighted patterns. Confrontation-wise, we paid attention to the time-framing, the use of the traditional planning tools into the French system, the Zone d'Amenagement concerté (ZAC) even if

¹ Please refer to the doctoral thesis "Collaborazioni Pubblico-privato e qualità delle trasformazioni urbane. Condizioni riferimenti e possibilità" to learn more on the case studies (Ariani, 2017). Other information about the cases can be found, among other references in scholar publication and official reports and documents (see the references).

with innovative keys, and the location in underused and distressed areas of the city. Each case gravitates around the idea of experimentation, in processes, procedure, and urban morphology. In table 1 we present the main data of each project.

Table 1 Practices Data

Project	Paris Rive Gauche	ZAC du Chaperon Verts. Arcueil	Ile de Nantes	Cité internationale de Lyon
Dimension	136ha	5,4 ha	337 ha	35 ha
Time-line	1991-2030 expected	2006-2018	1999-2030 expected	1985-2008
Main players	Paris Municipality SNCF (French National Railways) SEMAPA (semi-Public planning company) State arrondissement (local district) Caisse des Depots et consignations	Communauté d'agglomération Val de Bièvre ANRU Caisse des Dépôts et Consignations Logement Foncière SADEV 94 TVK Architectes	Nantes Municipality Nantes Métropole SAMOA Atelier de l'Île de Nantes : Arch. Chemetoff (phase 1), Arch. Smets-Depuyts (phase 2).	Lyon Municipality Métropole de Grand Lyon Renzo Piano Building Workshop SARI-Compagnie Générale des Eaux SERL (Société d'Equipeement du Rhône et de Lyon) SEM de la Cité Internationale
Venture	Public. Paris Municipality	Public: Communauté d'agglomération Val de Bièvre	Public: Nantes municipality (main role played by the Mayor) .	Public: Lyon municipality (main role played by the Mayor)
Strategies and goal setting	Public players, big role of experts	Public, with a strong role of experts, local semipublic planning agencies and planners	Public, with a strong role of political strategy and capital	Public, with a strong role of experts, local semipublic planning agencies and planners
Collaboration type	ZAC for the whole area, and specific procedures created for the main project's nodes	Traditional ZAC within a national renovation program	Strategic framework lead by the public. Each different area of intervention delivered through specific development processes	Traditional ZAC within a national renovation program
Participation and concertation	No participatory processes, only information and	Strong participation in each project phase to define main	Strong participation in the early stages of the process	Strong participation in each project stage to define

	consultation	design issues		main design issues
Funding	Starting funds were public (through the SEMAPA capital). Then the financial balance was granted by traditional ZAC land transfer mechanism and private investors	Public starting funds (through the SEMAPA capital). Afterward, financial balance granted by traditional ZAC land transfer mechanism and private investors	Public starting funds. Long term financial balance granted through land transfer and fiscal revenues. Some of the project where market-driven once the development mechanism enhanced the area.	Public starting funds. Then the financial balance was granted by traditional ZAC land transfer mechanism and private investors
Land ownership	Mainly owned by SNCF	Mainly publicly owned	Fragmented land ownership, private and public	Mainly publicly owned

General principles and expected goals could be summarized as follows:

- *Paris Rive Gauche*: rehabilitation and requalification of an industrial fringe through the mending and physical reconstruction of the urban fabric. A new meaning for an important portion of the city with functional mix and land use variety set by the establishment of (public and private) service and facilities at an urban, metropolitan or regional scale.
- *Arcueil Chaperon vert*: rehabilitation and requalification of a distressed public housing district through physical opening up of the urban fabric and support of use and social mix. Organization of public national funding (Program national pour le Renouvellement Urbain, PNRU) together with attractiveness for private funders and developers.
- *Ile de Nantes*: regeneration and requalification of a big industrial fringe and the working class neighborhood developed in close relations with the former shipyards and industries. The project is based on the creation of a cultural and institutional framework at the city scale, thanks to the promotion of a new urban identity and city marketing. Incremental transformation based on consensus building, pervasive intervention on public space, and more generally sustainable development and creative and cultural economics city as main tools to enhance the area.
- *Cité Internationale de Lyon*: Regeneration and requalification of an underused area through services and facilities at the national and metropolitan scale, to create a pole of attraction in the area at the border of the city. Private investors' involvement through experimental procedures, aiming to be a model to be used in future projects. Strong political power that started a city marketing strategy to put Lyon on the urban European network radar.

Using the parameters presented in the previous chapter, it's possible to briefly describe the cases as in the following tables and then evaluate each item to pinpoint the main patterns.

The first series of tables (table 2-5) describe the independent variables for each practice.

Table 2 Paris Rive Gauche independent variables

Variables	Paris Rive Gauche
Time and duration	The project is organized in various subsections, developed through the years, with the capacity to adapt goals and procedures to the evolving conditions
Responsibility and public oversight (goals)	The goals are defined with public oversight, through the role of SEMAPA, initially a Single Purpose Vehicle. The real estate market, though, played an important role as the main tool to guarantee financial balance
Selection of players and their role	The private players, developers, funders, and construction companies are selected on an economic basis through public bid. There has been some exception with direct procurement process. While the planners were chosen through competitions, architect and designer were chosen by developers (as the project was part of the bid)
Land management	Operation's financial balance is based on land market, so it was influenced by real estate market. Recent tools try to control speculation. At first, the public agency had to face big initial funding for urbanization costs, forecasting to balance them selling and allocating land.
Risk sharing	The risk was mainly taken by public players. Private stakeholders followed market logics.
Control and coordination	<p>Projects are designed following the "Cahiers des Charges" tools drafted by planners and coordinating architects (one for each subsection, and then more specific ones for each lot and building). They are validated and controlled by SEMAPA and Paris Municipality. This allowed a specific focus on urban scale design features. In the most recent documents, there is special attention to sustainability. In land-disposal agreements, datasheet and Cahiers des charges, with minimum performance and feature for each parcel, in term of architectural quality and relationship with the urban context, are attached.</p> <p>The building license is granted upon the respect of such technical features.</p> <p>The public realm is designed directly by public authorities.</p>

Table 3 Chaperon Vert Arcueil independent variables

Variables	Chaperon Vert Arcueil
Time and duration	Short term implementation because of the low complexity of the intervention
Responsibility and public oversight (goals)	Oversight was strongly public, thanks to the participation to a national regeneration program for public housing
Selection of players and their role	The private players, developers, funders, and construction companies are selected on an economic basis through public bid, using traditional procedure within ZAC. Public stakeholders played the main role in the whole operation
Land management	Operation's financial balance is based on land market of privatized parcels, so it was influenced by real-estate market. Traditional procedures were enacted.
Risk sharing	The participation to the national program controlled the risks upon public players. Private developers were subject to market rules, within a clear procedure and sure outcomes thanks to public commitment.
Control and coordination	Projects are designed following the "Cahiers des Charges", tools drafted by coordinating architects (specific for each lot and building) attached to concession agreements. The main focus was on formal aspect and urban fabric defined by the masterplan. Building retrofitting on public housing was implemented by public players, therefore without the need for a specific control.

Table 4 Île de Nantes independent variables

Variables	Île de Nantes
Time and duration	Project meant for a long duration, organized in different phases that involve the whole intervention area (all the island). Incremental planning approach to the project favors the organization in the long term.
Responsibility and public oversight (goals)	Oversight coordination and control entrusted to the public agency SAMOA, single purpose vehicle. A strong political capital moves the whole project.
Selection of players and their role	Private players and investors are selected through negotiation procedures based on quality and sustainability. Designers' choice is jointly made by SAMOA and developers.
Land management	The land management is a policy tool, used by the SAMOA to plan and control specific projects. But it's not the only one, as a lot of parcels are private
Risk sharing	Negotiation and transactional procedures allocate the risks evenly between public and private. Positive outcomes of procedures are guaranteed through the follow up by the public players.
Control and coordination	Technical operative tools like the Cahiers des Charges are the results of negotiation with private developers and are discussed and drafted during the tender procedures There is a specific focus on sustainability, but also on the functional mix and building density index (usually lower than the ones defined by the higher planning documents). When developers are the owner of the land they are not required to talk with the public agency, but only negotiation grants the positive outcome and the building permit release.

Table 5 Cité Internationale Lyon Independent variables

Variables	Cité Internationale Lyon
Time and duration	Evolution of the project during the time was not expected but due to external causes (mainly economic)
Responsibility and public oversight (goals)	During project development and implementation, oversight and control were taken over by both private and public authorities. Project consistency and relationship with public decision makers were granted by SEM Cité Internationale, small public authority specifically created for the project
Selection of players and their role	Players were chosen mainly by economic criteria. Renzo Piano Building Workshop was the main designer and accountable for the urban project, chosen by political decision-makers and responsible for the quality and consistency of the project.
Land management	Land management was at the core of the transactions to involve private stakeholders. This strongly influenced the mix of uses.
Risk sharing	Due to the strong role played by private stakeholders, they took most of the risks.
Control and coordination	Renzo Piano drafted the Cahier des Charges, the main tool to coordinate and control the whole operation; this granted the consistency of the project. It was a well-defined preliminary design, attached to building permission contractual agreements. Furthermore, it was required by the public authorities that RPBW was the main designer of every building, in order to guarantee quality and consistency. For this reason, further controls weren't required.

Similarly, we applied the same analysis on the outcomes of each case, following the Forms and output set... They are summarized in the following tables (tables 6-9)

Table 6 Paris Rive Gauche dependent variables

Forms and outputs (dependent variables)	Paris Rive Gauche
Goals-outcomes consistency	General goals at the city scale were the constant of project development. Subsections goals were mainly related to physical, spatial and architectural issues, and they evolved during the time
Public Spaces	Dimensions: Green public spaces are small compared to the whole area. Public space is mainly at block scale or connection and sidewalk but it was also implemented the requalification of Seine's docks.
	Functions and uses: The lack of big public space is balanced by the spreading of public facilities. The university campus in Massena subsection has the biggest and most equipped public spaces
Accessibility and mobility	The area is well located in relation to the city, with strong public transit infrastructure implemented within the project
Urban fabric and architectural quality	The dense urban fabric is based on traditional Parisian Boulevard plot, made by compact block. Some experimentation in urban design was implemented in Massena subsection (Portzamparc's Ilot ouvert). There is a great amount of high-quality building and landmarks
Facilities, urban function and neighborhood's identity	There is a good balance among, housing, directional building and public facilities that were developed during time. The mixed housing policies were not helped by the retail and offices building that favor gentrification. A network of metropolitan scale functions and facilities was put in place as one of the main goals of the project.
Externalities and other outcomes	The operation created a new metropolitan pole in the Parisian East sector. On the con's side, the neighborhood is producing gentrification processes

Table 7 Chaperon Vert Arcueil dependent variables

Forms and outputs (dependent variables)	Chaperon Vert Arcueil
Goals-outcomes consistency	The project reached the goals of redeveloping the public housing neighborhood through physically opening up the area and creating a social mix with private investments
Public Spaces	<p>Dimensions: The requalification of the central square is the core of a widespread system of local-scale public and green spaces. The system is linked with an inter-municipality linear park</p> <p>Functions and uses: Public spaces are for the neighborhood's dwellers. Focus on connections between spaces and with surrounding neighborhoods.</p>
Accessibility and mobility	There was no new public transit infrastructure within the project. Nevertheless, the spatial opening up of the neighborhood improved the pedestrian accessibility
Urban fabric and architectural quality	Densification and public spaces' requalification improved the overall urban quality and perception of the neighborhood. Public housing was improved through energetic retrofit, while the private building attained to high-quality tech and sustainability goals.
Facilities, urban function and neighborhood's identity	Mainly housing, with the improvement of local facilities and retails. The mixed housing stock favors the social mix and improved the neighborhood's identity
Externalities and other outcomes	The neighborhood opened to the surrounding areas, beyond the public housing stigma. The project is part of a bigger transformation within the Grand Paris metropolitan plan

Table 8 Île de Nantes dependent variables

Forms and outputs (dependent variables)	Île de Nantes
Goals-outcomes consistency	The general goal was to transform an underused area in a competitive and attractive node in the city, and it was overall achieved. The specific goals and steps have been defined incrementally and with constant feedback.
Public Spaces	<p>Dimensions: The public spaces are widespread across the area and big parks and green spaces have been developed in the island's edges and in general the project redeveloped all the docks. The intervention area, with new buildings and development, is marked by special attention on public space, while this aspect is overlooked in the older parts of the area</p> <p>Functions and uses: Public spaces are the focal point of the development project. Universities and landmark artworks, as well as thematic park, are the main identity of the neighborhood.</p>
Accessibility and mobility	The new light rail train infrastructure was the starting point of the whole project. Nevertheless, the infrastructure is not sufficient yet to cover all the area
Urban fabric and architectural quality	In the industrial fringes and underused areas, the project established a strong densification, of buildings and uses. The incremental approach to the project allows layered and diversified urban design. Building and public spaces are designed with high architectural quality and a strong focus on sustainability
Facilities, urban function and neighborhood's identity	It's a big project on a wide urban area, partially urbanized; therefore in the area, there is already a big variety of uses. The project improved the diversity of uses and mixed housing development. To improve the role of the area, the project developed a network of metropolitan scale facilities and infrastructure, both public and private, connected with knowledge economy and creative cluster
Externalities and other outcomes	Due to the huge dimension of the operation, the project developed a new metropolitan pole. At the same time, the improvement in competitiveness started some gentrification process.

Table 9 Cité Internationale de Lyon dependent variables

Forms and outputs (dependent variables)	Cité Internationale de Lyon
Goals-outcomes consistency	The general goal was to define a model in urban project procedures, but this goal was neglected because of the peculiarity of the procedure that couldn't define a general guideline. The functional mix has changed to follow the evolution of players network
Public Spaces	<p>Dimensions: most of public spaces connect the buildings, such as pedestrian central axis and the big public plaza. The big park along the river, besides being within the area of intervention, is not well connected with the main project. Just outside the area, there is a historic public park that adds value to the area.</p> <p>Functions and uses: The central pedestrian street is the focal point of the spatial development and of the urban design.</p>
Accessibility and mobility	New light rail train has been developed, the public transit infrastructure was crucial in project development.
The urban fabric and architectural quality	The financial balance of the project was granted by intensive development. Renzo Piano was the designer of all the main building and of the overall urban design. This approach granted architectural quality but not as much diversity
Facilities, urban function and neighborhood's identity	The functional program is very simple, centered on hospitality, conferences and commercial sector, the main focus of the business center. To balance the uses, there is some housing too.
Externalities and other outcomes	New metropolitan scale business center had some effect on the role of the city in the European network. Because of location and uses, the neighborhood is still isolated from the rest of the city

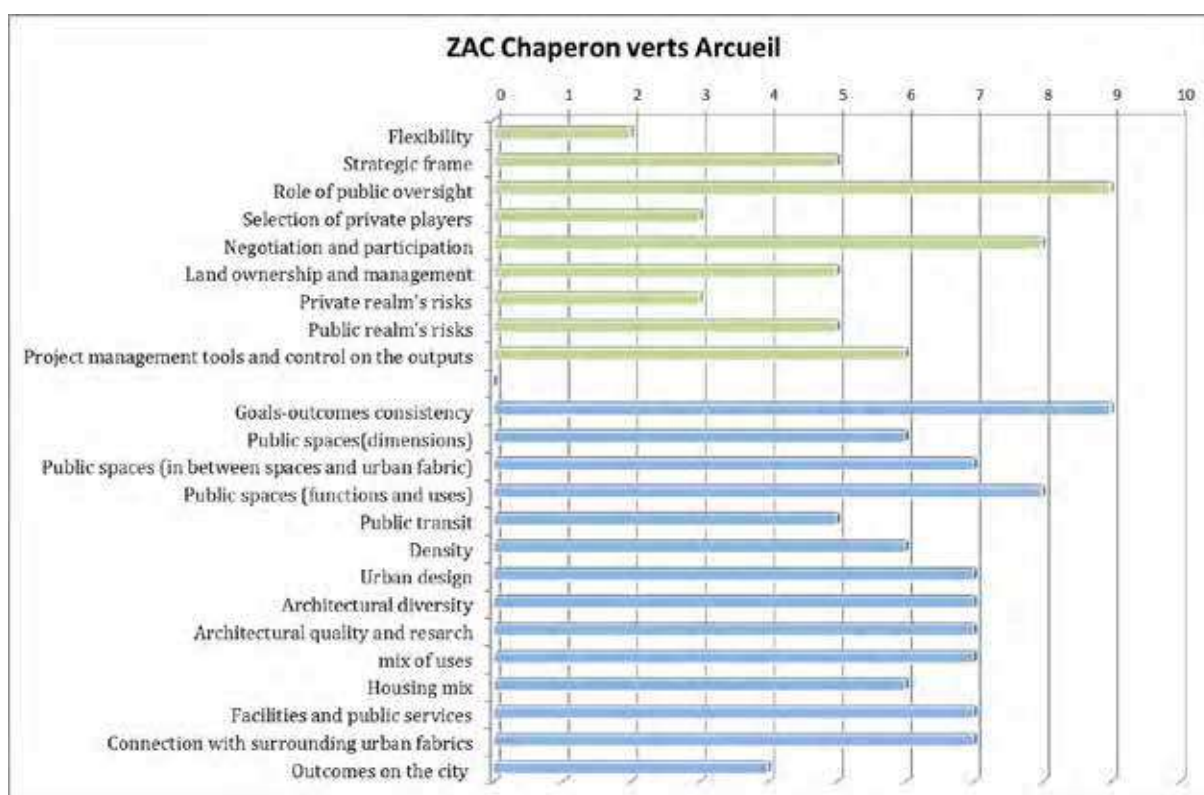

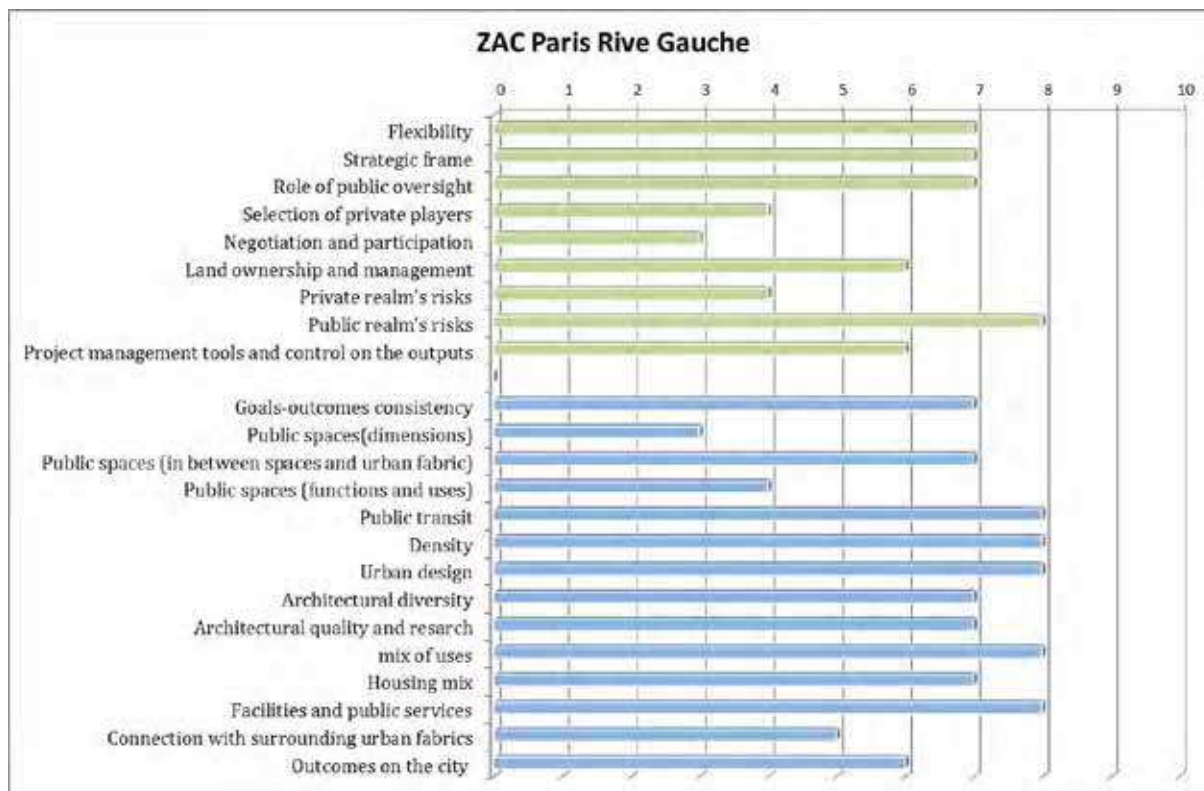

Comparative analysis and pattern definition

In the following tables, again we analyze each practice through the independent and dependent variables, this time proposing an evaluation of each item in order to frame them in the comparative studies with the use of indicators and variables. The processes are read as independent variables that shape the PPCs, while the outcomes are dependent variables so that this model can highlight the main patterns.

Parameters			ZAC Paris Rive Gauche	ZAC Chaperon verts Arcueil	Ile de Nantes	Cité internati onale Lyon	EVALUATION CRITERIAS
VARIABLES	Time and duration	Flexibility	7	2	9	5	project adaptability in the time framing (0= min, 10=max)
		Strategic frame	7	5	8	7	project assimilation within long term strategic frame, at metropolitan or regional time (0=irrelevant, 10=essential)
	Responsibility and public oversight (goals)	Role of public oversight	7	9	9	7	Public oversight relevance in goals' definition (0=min, 10=max)
	Selection of players and their role	Selection of private players	4	3	8	3	players' engagement rules in transformation processes (0=solely economics, 10=solely qualitative)
		Negotiation and participation	3	8	7	3	relevance of negotiation and of participatory processes in project's definition (0=irrelevant, 10=essential)
	Land managment	Land ownership and management	6	5	8	3	purpose of land ownership leverage (0=solely economics, 10=complex project management)
	Risk sharing	Private realm's risks	4	3	5	7	Fair distribution of business and financial risks (0=only at public players' expens, 10=only at private players' expense)
		Public realm's risks	8	5	5	4	Fair distribution of business and financial risks (0=only at public players' expens, 10=only at private players' expense)
	Control and coordination	Project management tools and control on the outputs	6	6	8	7	Public oversight's capability on outcomes ' quali (0=none, 10=high and well-structured in complex procedures)

Parameters			ZAC Paris Rive Gauche	ZAC Chaperon verts Arcueil	Ile de Nantes	Cité internationale Lyon	EVALUATION CRITERIAS
Forms and outputs (dependent variables)	Goals-outcomes consistency	Goals-outcomes consistency	7	9	8	7	Consistency between goals and final outcomes (0=min, 10=max)
	Public spaces	Public spaces (dimensions)	3	6	8	4	Extension of public space in relation to the whole intervention's area (0=small, 10=big)
		Public spaces (in between spaces and urban fabric)	7	7	6	8	Quality of small spaces and connective areas (0=low, 10=high)
		Public spaces (functions and uses)	4	8	9	5	Relevance of public spaces in overall project quality (0=irrelevant, 10=essential)
	Acessibility and mobility	Public transit	8	5	6	8	Increase in infrastructures for public transit (0=none, 10= high)
	Urban fabric and architectural quality	Density	8	6	6	8	Urban density and balance after the implementation (0=low, 10=high)
		Urban design	8	7	9	8	Urban design quality (0=low, 10=high)
		Architectural diversity	7	7	9	4	Research on architectural innovation and diversity (0=low, 10=high)
		Architectural quality and resarch	7	7	8	8	Technical qualties and innovation in architecture and built environment (0=low, 10=high)
	Facilities, urban function and neighborhood's identity	mix of uses	8	7	8	5	urban quality due to mx of uses (0=low, 10=high)
		Housing mix	7	6	8	2	diversity in the housing stock and distribution of public housing,market rates and other housing solutions (0=low, 10=high)
		Facilities and public services	8	7	8	5	Relevance of infrastructure, facilities and public service in the definition of the project and implementation (0=low, 10=high)
	Externalities and other outcomes	Connection with surrounding urban fabrics	5	7	7	6	Risk fo speculation and negative externalities on the housing market due to the implementation (0=high, 10=low)
		Outcomes on the city	6	4	8	7	outcomes on the overal urban environment (0=extremely negative, 10=extremely positive)

This evaluation led to some graphical synthesis that made clear some of the patterns that we will use to define the general guidelines for a better Public-Private Collaboration. We can read each case, highlight the strength and weakness, and we can also easily compare the four practices and suggest some ideas on what works better in French planning tradition.

Independent variables (processes)

Dependent variables (forms and outcomes)

Public realm as a whole, including transportation, facilities, and accessibility, reached good quality in all the projects. Anyway, traditional ZAC procedures, as Paris Rive Gauche and Cité Internationale de Lyon gave a less prominent role to public space in the project's concept; it happens because the land ownership is mainly market-driven and aimed to financial balance. Nevertheless, we have observed that urban design and small-scale public space is still important, helping the real estate market. Arcueil and Nantes showed an effort in participation since the early design stages. In these cases, public space has a main role in the project and in the construction of neighborhoods identity.

Public oversight is central in all projects, even if interpreted in different ways; there is a general consistency between goals and outcomes. Every project is designed within a bigger strategic framework, space-wise and time-wise, regardless of dimensions and complexity of the projects. There is no linear correlation between public-private risks allocation and the importance of public oversight. That means that the definition of public interest can be a framework within which private actors can play a role and enjoy the advantages.

A better collaborative process matches with general outcomes' quality. In Nantes, inclusive processes and participation is the main part of the collaborative process and it shows in most of the outcomes. Even less inclusive examples, as is Lyon was possible to reach a good evaluation and excellence for some specific parameters. The role of the *aménageur*, the subject that plays a pivotal role among public and private stakeholders, it is different in each case, but it is crucial in influencing the implementation of private development projects through tools and documents as *Cahiers des Charges* and *Fiches de Lot*. The use of such tools matches the general strategic approach and translates principles and goals into working projects.

Urban form and its design, architectural quality and research on urban design reach good quality in all of the four projects, even if it is not possible to find a specific correlation with single indicators, and we can assume that these results are consequences of different processes.

To sum up, the strengths and opportunities highlighted by these patterns allowed to translate what we've learned from the case study into the guideline to improve collaborative urban transformation.

Public-Private Collaboration potential

The city is public, or it's nothing. The city is public beyond the false opposition between public and private, and the private actions within a collaboration process have to be traced back to a general idea of public interest. The city is public to the extent that public action brings back private action to the goals that the city defines for itself. With this key, it's possible to say that Public-Private Collaboration is an inherent part of the production of the city.

Mandates and agreements with private stakeholders have always been part urban growth. The private development is an opportunity even when it doesn't aim to give back something to the public city... The private development is a trigger for urban regeneration and the pursuit of public interest. Thanks to public steering, it is possible to go beyond public-private dualism and economic competition's logic. Project's quality is in the mix between public and private interventions: this allows risk sharing too. When this happens there is no simple offsetting but complex dynamics that favor the achievement for shared quality goals. If the private take the risk, the outcomes will comply with quality standard, to be sure that the invested capital will return, and with a gain.

From the case studies, it was possible to define the following general principles, in order to connect strategies with practices in urban development. It is a general exposition that can be a starting point for the definition of guidelines to translate the peculiar French planning practice in other contexts.

Multitemporality; multi-layered timing in transformation as an opportunity. Talking about multi-temporality means look at the duration, the time needed in urban transformations, as potential, and not as a negative

externality. In the eye of the private investor, the economic revenue, due to selling or renting estates, is the main priority, and the sooner the better. The public actors should move in a different time frame: the effort is to support a wider transformation and to make a change in the city, and not only in view of the short term polls feedback. Multi-player urban transformations need to put together the short term pragmatism of the free market with the public policies, which usually need a long term to be fully developed. As is space, time is a frame but also a tool that needs to be used and interpreted to coordinate and define planning and design stages of an incremental approach, by highlighting priorities, evaluating feedback from halfway outputs, improving the outcomes' quality. Multi-temporality can be an opportunity when it pairs with a multi-player asset and connects with background adaptability, where a clear definition of the players' roles allows the adaptation of plans and design to the evolution of the environment and urban context. Project's adaptability, even within consistency in the answer to demands, is the working face of multi-temporality as an added value to the project.

Public Oversight and shared responsibility. A public oversight and control it's a necessary, but not a sufficient, condition to coordinate private interests, create experiments, search for identity, production of a good quality city, where public and private could interact in synergy. Market and planning are not always forces meant to collide. The legitimacy of the control is given by the pursuit of public interest, therefore PPC can be a place for debate and confront, where bargaining logics will leave space to deliberation. To avoid the prevalence of market-oriented dynamics, it's important to define the goals clearly and to allow negotiation and consultation in every development's stage, and put together conflicted issues in order to create opportunities. There are multiple layers of control, and oversight: starting of the project, land ownership, land use, project management, control of the outputs. Anyway, purely top-down control and decision making could be against PPC multi-player approach; responsibility reallocation is necessary for the public oversight to gain resources and expertise, in exchange for an environment favorable to the development of private interests. Deliberation, rooted in the idea of debate to pursuit a shared decision beyond the purely quantitative idea of majority, aims to be a space to find an agreement between criticality, rather than erase conflict (that is natural when many players are involved).

Responses consistency with needs demands and issues from the citizens and the territory. PPCs should be able to systematize the interests of involved players, framing them in a bigger picture, picking up the complexity of redevelopment and regeneration processes as well as players' expertise and resources. With PPCs, it's possible to change the point of view: in the definition of the final goals, operations in the public interest are object of negotiation. In this way, financial balance is a precondition for the feasibility, not the final goal. Hence, it's important to analyze the influence of private players, that usually are developers and construction management firms as well as banks and investors, big stakeholders not always transparent enough, and whose interests are not always linked to the general interest frame that should be pursuit by public sector agencies.

Clear goals' identification. Considering the search for consistency, the final goals of urban transformation should be identified without ambiguity, highlighting how PPC implementation can contribute to their achievement. Well defined goals are not opposed to the need for flexibility inherent in multi-phased, multitemporal project development. On the contrary, clear goals within a broader frame allow space for adaptability and changes in each project action during a long multi-temporal process. Consistency is guaranteed by the oversight of the project, keeping market-based actions within the public interest ratio. The more the process are complex, the more is important sharing strategies in order to achieve general interest's objectives, So, goals become the linking element between strategic and operational dimensions. Goals' explicitness brings to identify more easily the technical features and procedural steps that each project need to fit in the general frame. The clear goals, result of shared and complex processes, are useful both to identify the oversight responsibilities and the evaluation of the good outcome of the processes. When goals are consistent and clear it is possible to communicate and share them with players and user; goals are crucial to assess the effectiveness and accountability of CPPs.

Framing these approaches in a more complex picture and highlighting the connection between processes and outcomes can be the enhancement element for a good PPC implementation. These approaches could be interpreted as boundary objects, connections between public and private areas of interest, in order to design a frame where conflict among paradigms, interests and quality's definitions can be rebuilt and interpreted to innovate. The world is changing, and we need to look for a different interaction between public and private, within the search for new sustainability in a changing society. Giving that PPC is going to stay, as one of the main approaches, and maybe the most natural in the production of the city, we think that we should go radical in the form of collaborations. We suggest applying this evaluation method to more cases and practices, to highlight more patterns, and to confront the potential within different countries' tools box. We strongly believe that this methodology of evaluation can be further enhanced with a broader comparison within a large set of experiences, best and worst practices in Europe, in order to build a comparative basis to learn how to do better and what to avoid in order to build a more just city.

Abstract: New geographies of urban development have been emerging, as a result of the interplay between global driving forces and local socio-economic and institutional conditions. In Central Italy, the influence of the city of Rome has gone beyond the administrative limits and of the Daily urban system traced on the basis of commuting flows. The urban geography of Rome has, no longer, a radial structure, new spatial and functional interdependencies are emerging in a vast and low-density city-region, expanded even beyond regional borders. This paper presents first results of a research carried out by the University of Roma Tre commissioned by the Lazio Region, whose aim is to investigate recent urbanization processes in the city-region of Rome under the above-mentioned perspective, adopting a multiscale approach, critically referred to international studies on the regional dimension of urban development, with an intentional mix of quantitative and qualitative methods. Since “conspicuous changes” are now emerging from a series of tactical and opportunistic assemblage, our aim is to underline the need of a renovated multi-level governance, to address the transition from assembling to agencing in terms of a more equal distribution of social and economic opportunities within the regional space.

Keywords: City-region; Multilevel governance; Assemblage; Agencing.

In the last twenty years, a plural reflection on transformations that have gone through the category of the urban opened up a new perspective over the regional and post-metropolitan scale of urbanisation. The reorganization at regional scale can no longer be looked at through static interpretive lenses, being configured as a process a dynamic of decomposition/recomposition of relationships between economy, society and territory, driven by the combination of inter/supranational forces and local factors. As highlighted by Brenner and Schmid (2014), polarization and extensive urbanization coexist in a continuous process of urban re-writing, through processes of differentiation and standardization of the territory, implosion and explosion affirming new forms of urban life and types of spatiality (Balducci *et al.*, 2017, p. 18).

Similar dynamics occurred in the regional area of Rome, later than in the northern part of the country where a regional polycentric structure already emerged in the Sixties (Moroni 1969, p.11-15) and was deeply analysed in relevant well-known studies (Lanzani and Pasqui 2011, p. 39-40). On the contrary, the new territorial dimension of urbanization in the Roman area - arose from the joint impulse of a real-estate cycle started in the 1990s and of the economic reorganization influenced by national and international drivers - is so far partially unexplored. As a result of a centrifugal process of inhabitants

and activities, the urban system is nowadays extended at a large scale (on first approximation, within an area of 100 x 80 km) and reorganized through corridor dynamics along the transport backbone. Moreover, the influence of Rome has expanded on an even wider area that goes beyond physical boundaries of the conurbation and the perimeter determined by daily movements between home and workplace. Flows of people, goods and knowledge are spread in a basin extending up to Umbria and Abruzzo, where six million people live, work and spend their free time.

Need for a different descriptive-interpretative model. Rome is a city in transition, going through a particularly complex phase of change. The weakening of its function of political capital, which so far determined the economic and social base of the city, necessarily leads to reflect on possible actions of contrast to the decline (Tocci, 2015; Caudo, 2017) and measures to accompany the transition towards a new phase (Coppola and Punziano, 2018). However,

«Rome as Capital City has not managed, until today, how to go beyond the idea of a big city which attracts a large number of civil servants and inhabitants who need houses» (Caudo, 2018)

It's therefore necessary to abandon this dominant perspective that has leaved in the shade what happened outside the city. The regional dimension of urban development has become the proper area for the interpretation and the governance of change. This is the reason of an ongoing research commissioned by the Lazio Region and carried out by the University of Roma Tre, whose first results are presented in the following paragraphs.

Metropolitan Core and Capital Region: a needed distinction

From the metropolitan Core... A decades-long tradition characterizes studies on the delimitation of urban systems based on physical and functional integration between contiguous territories. The plurality of criteria that can be used to define metropolitan areas, due to the different possibilities of conceptualizing "territorial interdependence" (Calafati, 2014, p. 5), leads to different outcomes. In the Roman case, however, there is a convergence around the delimitation of a *metropolitan core* whose shape and dimensions are to a large extent superimposable with those of the Province¹.

	Area kmq	Municipalities n.	Population 2011 *1000
Provincia di Roma (+)	5.363	121	3.997
FUA Eurostat (*)	6.165	159	4.066
Metropolitan Core (#)	6.607	171	4.146

(+) Legal population, Census Data. (*) Eurostat data, reported in Istat 2017, p. 316 (#) Our elaboration, on Census data

Table 1. ISTAT data 2011 processed by the authors

... to the Capital Region. Starting from a study by Paolo Veneri and Rafael Boix (2009) - based on criteria for the delimitation of metropolitan areas which, although being referred to systematic commuting, are more sensitive to the interdependencies on the macro scale - we have extended the field of observation to include the functional areas of Viterbo, Terni, L'Aquila and the local labour systems of Rieti and Avezzano². The use of mixed criteria was necessary to circumscribe an

¹ According to the 65-2014 law, the metropolitan city administrative boundaries coincide with the former province limits.

² Rieti and Avezzano are small cities not considered in FUA (Functional Urban Area) delimitation. However, being located in mountain areas, they play a significant role – under a socio-economic point of view – for a large

appropriate area for investigating the quality of the economic and social relations with Rome, even if the delimitation of a precise boundary escapes univocal determinations (Balducci *et al.*, 2017 p 18).³ In our work, we define as “Capital Region” this new framework within which fruitful relationships with Rome can be unfold and governed.

	Municipalities n	Area kmq	Population 2011 *1000	Density ab/kmq
Rome (inside the motorway ring)	1	345	2.100	6.000
Rome Municipality	1	1.287	2.617	2.030
Province/Metropolitan city (NUTS3)	121	5.363	4,353	810
METROPOLITAN CORE	171	6.607	4.146	630
Lazio Region (NUTS2)	378	17.232	5.892	340
ROME CAPITAL REGION	471	22.132	5.935	270

Table 2. ISTAT data 2011 processed by the authors

Figure 1. Metropolitan Core, Dynamic metropolitan area of Rome, Capital Region.

number of municipalities (both fall within the larger 10 out of 661 local labour system in Italy, according to ISTAT).

³ ISTAT proposed the identification of 35 “Functional region” to investigate “the consistency of relations and exchanges between Italian cities” (ISTAT, 2017, p. 99). The functional region of Rome is largely superimposable with the Capital Region, with the exception of Terni, aggregated to Perugia. This divergence is representative of blurring borders. *Dynamic Metropolitan Area* method, proposed by Clusa and Roca and adapted and tested by Paolo Veneri and Rafael Boix (Veneri and Boix 2009) in a comparative study between Italy and Spain, presented at IERM in 2009. The DMA can be seen as an *in-between* space.

Rome Capital Region: the overall strength

About half of the population of the Central Italy⁴ live in the Capital Region. Since 1951 until today, the number of inhabitants increased by more than 2.5 million, equal to 75% of the overall increase recorded in the six Regions of the Central Italy. Consequently, the weight of the Capital Region increased from 36.5% to 46%. Within the Capital Region, the weight of the population of the municipality of Rome from 1981 to 2017 remains almost unchanged (2.8 million), while the greatest growth is recorded in the *metropolitan core* (from 3.7 to 4.5 million), witnessing a strong process of counter-urbanization.

From an economic perspective, in the Capital Region:

- more than half of companies of the Central Italy (500,000) have settled;
- the added value of the production (DARA, 2104, p.88) is higher than the Italian average, being the Province of Rome is the third metropolitan city by added value per capita (31.415 Euro, in 2014) and the second by total added value (134 billion Euro, in 2014);
- key productive sectors (biomedical, aerospace, telecommunications), having a high level of innovation/internationalization (Unioncamere Lazio, 2014, p. 19-20), deny the image of a capital city flattened on public sector and mass tourism;
- international logistics and trading players located relevant centres because of the advantages linked to the barycentric location along the North-South ridge and in the junction between the Tirrenian and Adriatic sides.

Distinctive outlines: three profiles of urban development

Rome Capital Region is not comparable with other Italian metropolitan areas. The interplay between the geographical and settlement features configures a rich and diversified space, totally peculiar, articulated in about twenty-five geographical sub-regions (Almagià 1966) and as many settlement systems (Menichini 1996) combined together. In the perspective of urban development, some profiles are particularly relevant: the emergence of an imperfect polycentrism, the consolidation of urban clusters influenced by dynamics of corridor and junction, the structuring of non-linear geographies reflecting complex spatial-temporal relationships.

Imperfect polycentrism. Although the low degree of urbanization (8.4%) and density of population (less than 300 ab/kmq), Rome Capital Region is characterized by the presence of a significant number of medium-sized cities (46 municipalities with more than 20,000 inhabitants), consolidated in recent decades and distributed in equivalent number between the metropolitan core and the Capital Region. This polycentric structure can be qualified as “imperfect”, because of the dominant role of the central pole within the functional region (Fardelli *et al.*, 2017, p. 107) and due to gaps in provisioning high and differentiated supra-municipal services detected in half of the cases.

Municipality inhabitants	1951	1981	2017
> 100.000	1	2	3
50-100.000	2	4	10
20-50.000	13	27	33
Totale	16	33	46

Table 3 Capital Region. Number of municipalities per class of Inhabitants.
Istat data processed by the authors

⁴ Central Italy is one of the 5 NUTS1 statistical group of regions, and it encompasses Toscana, Marche, Umbria, Lazio. By dividing Italy in three parts, geographically speaking, Abruzzo and Molise can be considered part of Central Italy.

Corridor dynamics. Next to this urban structure, sparse and imperfect, new settlements - specialized for the large distribution, the *loisir* and the logistics - interest both main industrial poles, planned in the Seventies within the framework of industrial development policies for the Southern Italy, and minor industrial zones planned at municipal level and afterward adapted to encompass new functions. A well recognizable logic of corridor, intended as an urban development dispositif (Garavaglia 2017, p. 59-62), pushed the reinforcement of the regional urban system along the internal axis Orte-Fiano-Valmontone. The national motorway network is here also the backbone of regional transport and, at one time, allows to serve the local catchment area and to reach the central-southern area (especially the Neapolitan area, almost equivalent in terms of population compared to the Roman one). The interplay between the new geography of specialized settlements, concentrated in valley floors and coastal plains, and the old structure of historical settlements along the consular and ridge roads, shape new territorial figures (see Figure 2), whose traces are visible from commuting lines (Vazzoler, 2016), although not representative of important non-systematic flows of goods and people.

Non-linear geographies. Over a time period of forty years, Rome experienced a decrease of 800,000 inhabitants in the central areas, compensated by population growth in peripheral districts. The *Raccordo Anulare*⁵, conceived as the external ring around the city, today constitutes an intermediate axis of the *metropolitan core*, considering that 2.000.000 people are living inside it, and almost 2.500.000 outside. Without questioning the weight and role of the central city, the regional territory can no longer be interpreted using linear descriptive models based on the dichotomy centre/peripheries. Spatial patterns of inequalities and vulnerabilities do not follow univocal trajectories, both within the *metropolitan core*, as well as in the *Capital Region*. Moreover, interpretations based on the contrast between central cities and rural areas, or on the hegemony of urban elites (D'Albergo and Moini, 2011, p. 5-27), have to be flanked by opposite reflections over the weak influence of Rome, inadequate to counterbalance local socio-economic fragilities.

The Capital Region as network of productive systems

According to a Censis-Unioncamere report (2010), companies and employees in the manufacturing, logistics, wholesale trade and high-tech sectors are concentrated in 13 clusters, whose formation and development is determined by a sum of interacting factors:

- consolidation of territorial supply chains (agri-food, boating);
- localization of large companies (mechanics, aerospace, pharmaceuticals);
- direct relations with the metropolitan area and with the supra-regional territory as a potential catchment area (wholesale, logistics);
- institutional initiatives (ICT, High-tech).

Recent researches (DARA, 2017) confirm that the *metropolitan core* constitutes the heart of a more extensive and solid productive system, involving industrial sectors in external counties (Latina, Frosinone, Rieti and, beyond the Lazio's borders, L'Aquila). For pharmaceuticals or advanced mechanics (aerospace), the trans-regional and metropolitan dimension produces relevant advantageous synergies for innovation and internationalization. Hence, the presence of a relevant number of small and medium-sized cities and dynamics of network connecting local production systems to advanced research and service centres concentrated in the central city, configure the Capital Region, at least potentially, as a *supercluster* (Scott, 2001). Therefore, the perspective of the Capital Region can be intended as a means to pave the way for new forms of collaboration between Rome and its regional territory, overcoming the limits of local development and the distortions of metropolitan polarization.

⁵ Grande Raccordo Anulare (GRA) is the common name of the motorway ring of Rome, built in the Sixties.

Figure 2. 2011 Commuting flows not towards Rome, and production clusters

Extract from Rome Capital Region– Research Report.

Towards an intentional assembling

Spatial territorialisation and the dialectic between opportunistic practices and inertial forces. The previous overview to the Capital Region is aimed to spatialize overall trajectories of change. Looking at a lower scale, substantial transformations directly related to the socio-economic reorganization mainly appear as physical reconfigurations and functional adaptations of the material legacy of previous cycles of urbanisation: national motorways (urban and regional commuting), specialised industrial settlements (tertiarization and recreational use), urban fabrics (repopulation of historic centres, abandoned farms and touristic apartments on the coast), agro-forestry land (productive intensification/extensification, diversification/fragmentation), natural areas and heritage (tourism-oriented functionalisation). These transformations, considered individually, appear as site-specific outputs produced by tactical initiatives, promoted by families or companies, looking for the maximum benefit achievable in the short period and on the given conditions. Public infrastructures and land-use regulation, both established decades ago⁶, perform more as constraints than as drivers of development. The dialectic between opportunistic practices and inertial forces produces implicit adaptive strategies (not discussed, nor evaluated in the public arena). As briefly above illustrated, due to their path-dependence, they don't seem able to counteract territorial fragilities and inequalities, nor to fully dialogue among each other, nor to contribute in a synergistic way to accompany the economic transition.

From assemblage to "agencing". From a more theoretical point of view, these dynamics can be interpreted under the Deleuzian lens of assemblage (Deleuze and Guattari 1980). Moving through assemblages seems to be the dominant condition of the action: inertia and conditionings alongside

⁶ About 60% of municipal land-use plans were approved more than 30 years ago (Regione Lazio, internal survey).

uncertainty and movement in relation to external forces determine a specific space-time condition, pushing towards “short-sighted practicalism and expediency” (Hillier 2011, p. 504). As highlighted by Hillier, the movement from assemblage to *agencing* (intended as a process by which various entities are inter-connected and put in motion) is strictly related to the awareness about “opening-up or closing-off” potentialities.

Despite the importance of the transition from assembling to *agencing*, the domain of short time is persisting. Therefore, a question remains as to the specific capacity of spatial planning to address long term issues and strategic choices. The long duration has not disappeared, but the search for founding elements of permanence and persistence doesn't appear sufficient to give a real, pro-active role to spatial planning. This is why the greatest challenge lies in the capacity to act in the intermediate space between short and long duration, tactics and strategy, need and desire: a space full of contradiction and therefore of possibilities (Gabellini, 2018).

Within this framework, Roma Regione Capitale can be seen as an initial hypothesis to move on in the “zone of indiscernability” between “a form-that-is-no-longer and another form that does-not-yet-exist” (Hillier 2014, p. 514). At this stage, the main research focus is the setting of metaphorical images, giving an overviewed and differential vision, aiming to formulate proactive hypotheses about the future as a basis for the activation of new trans-scalar policies, capable to reconnect local diversity to the ambivalent characters of metropolitan polarisation. In the following steps, the main aspect to investigate is linked to the relationship of macro-level structures and micro-level movements and to the concept of scale, both as a capacity to read the transformation moving between the complexity and fragment, and as a meaning line capable of proceeding for socio-spatial-temporal concatenated jumps rather than being conceived as expansion.

Exploring IBA Basel – Assessing the impact of trilateral cooperation and the resulting perspectives for the post IBA period

Abstract: The International Building Exhibition IBA Basel is a non-formal planning instrument to improve cross-border cooperation and planning processes between Switzerland, France and Germany. The aim of IBA is to overcome territorial barriers of trilateral coexistence to enhance the quality of life in the region. As a catalyst of regional development, on-ground IBA projects seek to revitalize the spatial quality and improve the adoption by its users. Institutions, planners and civil society actors collaborate in the cross-border development and implementation over a period of 10 years. The outcome of the IBA process will be presented in an exhibition venue. Thus, scientific foundation, provided by an assessment that is based on a survey among involved actors, will substantiate the impact of initiated processes. The evaluation is supported by interviews and focus-groups that foster awareness for future challenges in the post IBA period. IBA may generate a remarkable leverage effect to regional development within the agglomeration, which is measurable on three interdependent levels of processes: activation and networking of actors, planning activities and projects and trilateral quality of space and life. A scenario for comprehensive development beyond the year 2020, would be an ongoing process of intensified exchange and cooperation across the region.

Keywords: International Building Exhibition IBA Basel, regional development, planning instrument, process evaluation

1. Introduction

The International Building Exhibition (IBA) takes place in the context of the trilateral agglomeration of Basel in Switzerland. IBA Basel was launched in 2010 with the aim to strengthen cross-border cooperation and development in the trilateral region. IBA is an ongoing process of 10 years of regional development, which is about to complete its last phase and finishes with the final exhibition in 2020 in the Vitra Design Museum in Weil am Rhein, Germany. In this regard, IBA Basel commissioned a scientific accompanying research in late 2018. The research is meant to substantiate the exhibition with scientific knowledge and at the same time, enables IBA makers to learn from a long process of development in the trilateral region. The final report will evaluate the IBA process and allows IBA Basel to give recommendations for the post IBA period to its partners and peers. This paper provides an overview of history, structure and process of IBA Basel in the context of trilateral development. Moreover, it highlights ongoing scientific research and the mixed-method research design. We will emphasize the research motives and introduce the heuristic model, which outlines the base for the impact assessment. The scientific questions respond to three hypotheses, which correlate with the levels of impact of IBA Basel. The paper presents insight as well as intermediate findings of early phases of exploration and quantitative research in 2019. Furthermore, it outlines preliminary results and underlines challenges for the post IBA period. Finally, the purpose of this paper is to introduce and disseminate the IBA format to a broader international audience, thus it lays emphasis on the significant characteristics of IBA as non-formal planning instrument.

1.1 The trinational region of Basel – 50 years of cross-border cooperation

The trinational region of Basel encompasses 250 cities and municipalities in the regional territory of the states of Germany, France and Switzerland. Nearly one million people live in the trinational agglomeration, about 60.000 of them are cross-border commuters (Trinational Eurodistrict Basel [TEB] a, n.d.). The city of Basel is located on the north-eastern border of Switzerland and the southwestern border of Germany adjacent to France. The border lines of the states overlap in the river Rhine in its border triangle.

The cross-border cooperation in the region of Upper Rhine is exemplary and has a long history (Wassenberg, 2015, Storbeck, 2016). It was initiated by local stakeholders in the city of Basel and resulted in the foundation of the first framework of cross-border cooperation, Regio Basiliensis, in 1963. However, this development enabled a more or less pragmatic cooperation (Storbeck, 2016). In the year 2000, the states of Germany, France and Switzerland institutionalized the cooperation and signed the Basel Accord which contained the agreement on cross-border cooperation (Trinational Eurodistrict Basel [TEB] b, n.d.). In the same year, the neighborhood conference was founded, which published a resolution in 2004 to schedule the formation of an Eurodistrict in the agglomeration of Basel. Finally in January 2007, the Trinational Eurodistrict Basel (TEB) was founded. TEB is an association with 80 participating municipalities and regional administrative bodies, which fosters cross-border cooperation to strengthen the regional cohesion in the agglomeration (Figure 1). The association consists of political and various professional committees (Trinational Eurodistrict Basel [TEB] c, n.d.). Ever since its foundation, TEB is eager to intensive cross-border cooperation in the trinational agglomeration. TEB aims for regional cohesion in a strong economic area and a high quality of life and livable environment for its citizens. In 2011 the TEB founded the office of IBA Basel 2020, which took over important themes of TEB and carried them on in three different fields of action: landscape spaces, urban spaces and living together (Trinational Eurodistrict Basel [TEB] b, n.d., IBA Basel b, n.d.).

1.2 IBA as a non-formal planning instrument

In Germany, the format of an IBA dates back to about 120 years of history. Originally applied to a delineated area with a focus on architecture and urban design, like in the case of the famous Weissenhof Estate from 1927 in Stuttgart, the instrument has been continuously developed and increasingly disseminated in particular within the last 20 years. IBA is supposed to address relevant future issues, which demand a shift of paradigm. Such issues are negotiated and solutions are developed in specific local or regional settings, which possess exemplary international relevance. Beyond the objective of exhibiting architecture and urban space, IBA has more and more progressed into a process-oriented format, which is supposed to trigger innovation in local and regional planning institutions and settings. IBA provides for a state of exception that may overcome existing rules and regulations in a planning period of 10 years of time (cf. IBA Memorandum, 2017). The format is outstanding and incomparable in the international scene. Very few formats which provide for a similar condition of a laboratory and a bottom-up approach can be identified (Reicher *et al.*, 2011). The unique characteristics of IBA constitute on the open approach for innovation and experiment, and the linkage of top-down and bottom-up development.

With the most recent IBAs in Germany and in adjacent European countries such as IBA Emscher Park, IBA Fürst-Pückler-Land, IBA Hamburg, IBA Stadtumbau, IBA Basel, IBA Heidelberg, IBA Thüringen and IBA StadtRegion Stuttgart, a broad variety of IBA practice has evolved. Yet, IBA is no mandated or licensed instrument, but can be declared independently by local and regional stakeholders with very divergent topics and concepts. As a consequence, every IBA is different and the very open format is continuously refined from one IBA to another. In any case, three strong pillars of IBA can be identified: Firstly, IBA is a planning process over a period of mostly 10 years. Secondly, IBA enables change by developing specific projects. Thirdly, IBA exposes its results in a final exhibition, which provides a common goal for all IBA partners from the very beginning (cf. feasibility study City of Munich: Landeshauptstadt München, 2019 / Figure 2).

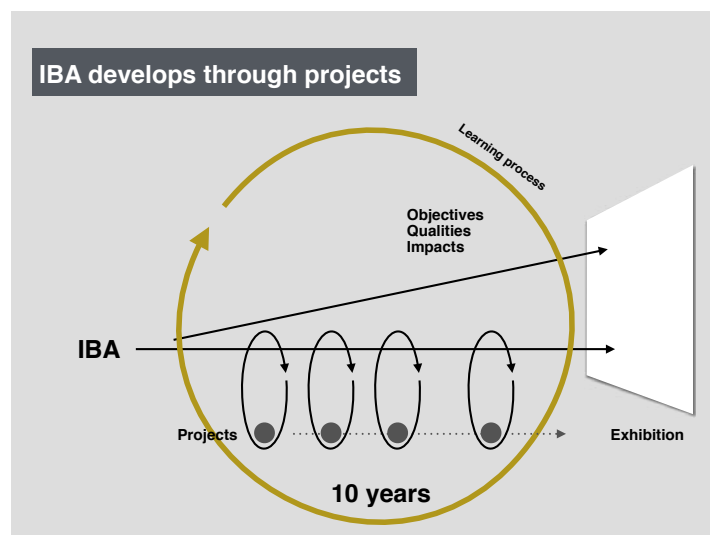

Figure 2: IBA as 10-years learning process throughout projects (Source: Förster and Petrin 2018)

The combination of these three pillars provide a coherent understanding for the specific IBA approach. Within the exceptional state of 10 years, projects are developed and continuously qualified. Under the umbrella of IBA, these projects follow a process of learning and innovation that simultaneously stimulates an overall learning for all IBA partners. The exhibition sets an ambitious goal at the end of that process. At the same time, IBA is an operational unit that delivers active project development, a communication and networking agency that brings together its active and operational participants, and an umbrella brand for the targeted marketing of its results (Landeshauptstadt München, 2019).

1.3 The IBA Basel process

The TEB decided to borrow the IBA format from the German planning context in order to intensify and enhance the cross-border cooperation within the region. IBA was anticipated to work as a catalyst to increase visibility of cross-border relationships and establish new multinational networks (Jann in Neuhaus and Marti, 2013). It was hoped that tangible projects would intensify and speed up joint urban and regional development at all sides of the borders. So far, the TEB primarily dealt with institutional and structural issues hardly visible in everyday life. With the launch of IBA Basel, the open call for projects invited all kinds of regional stakeholders to join the IBA process. This process took unprecedented efforts of communication between trinational actors.

The inauguration of IBA Basel 2020 was in mid-October of 2010 and initiated its bottom-up approach with a public call for projects in April 2011 (IBA Basel e, n.d. / Figure 3). This call released over 110 project proposals which were reviewed by the scientific IBA board of trustees in September 2011 by means of the established IBA criteria. The board gave recommendations for further processing of prequalified proposals and about 40 of these projects were presented again in November 2011 to institutional partners and the wider public in an open IBA forum. These projects were further developed in close cooperation with IBA. The first project show took place in 2013 and a three weeks exhibition was implemented from October until November with 43 IBA projects (IBA Basel e, n.d.). In 2016 an interim presentation took place and nominated 32 projects to remain on the agenda of IBA Basel.

Figure 3: Timeline of IBA Basel (Source: Author, following IBA Basel e, n.d.)

Starting from the interim presentation, IBA projects were structured in three fields of action: landscape spaces, urban spaces and living together (IBA Basel a, n.d.). In the course of the development remaining projects were partly categorized in project groups, for instance the Aktive Bahnhöfe and the IBA Rheinliebe. The groups should optimize and intensify the cooperation of IBA projects. All of these projects are going through the development in the 10-years IBA process, 18 of them are currently certified in the labellisation procedure of 2019. The final presentation in 2020, however, will exhibit the whole process of IBA Basel – with a broad spectrum of projects from the very beginning and a prospect for future-oriented goals and ideas.

IBA Basel is a special case in different aspects: IBA addresses a regional scale of cross-border nature with spatial, cultural, administrative and political barriers. The agglomeration of Basel, however, is a comparatively rich and growing region – in sharp contrast to other regional IBA processes that addressed painful structural change in shrinking regions as in the case of the Ruhr Area or Lusatio. As a consequence, a weak sense of urgency to cooperate beyond borders was a constant challenge in the IBA Basel process. Moreover, the IBA process was not equipped with a reliable financing over the 10 years period, but had to manage the uncertainty of three consecutive funding periods.

2. Research motives, heuristic model and leading questions

In the following sections, we explain our motives and hypotheses for the impact assessment and present the relevant research questions. Furthermore, we are going to highlight the importance of the research for comprehensive reflection of preceding years and the set-up of the post IBA Basel period. The research underlines an acknowledgement for benefits on enhanced regional development triggered by the non-formal planning instrument IBA.

2.1 2020 – A moment of reflection

In its 10-year process, IBA Basel activates actors, facilitates networking and supports projects with cross-border relevance. Based on this definition, we suggest that the relatively weak planning instrument of the IBA may generate a remarkable leverage effect to regional development within the trinational agglomeration. This effect can be identified already during the IBA process. It could be reproduced in the region, when initiated IBA projects become part of the spatial structure and are incorporated in future modes of practice and everyday life.

At the near end of the IBA Basel process it is time to reflect upon the initiated projects and moreover on the perspectives for involved actors in the post IBA period. The ongoing process of intensified exchange and cooperation across the region would be a major scenario for comprehensive development in the post IBA years. Thus, the attempt to push the IBA process far beyond 2020 has to start as soon as possible. It needs to foster the appreciation for the soft dimensions of multilateral networking, trust building and knowledge sharing beyond borders. The holistic reflection of this process can provide focused knowledge and consolidate an understanding of added value to the development of the trinational region. The integration of involved actors in this reflection is crucial for its results, hence the consistent update of the IBA process becomes more likely.

2.2 Understanding IBA Basel as structure and process for regional development

The general impact of IBA Basel on regional development can be examined when the structure of IBA is clearly sketched and its effort is translated into process. Our basic understanding of IBA Basel in its support for cross-border regional development was inspired by the St. Gall Management Model (cf. St. Gall Management Model in Rüegg-Stürm and Grand, 2002 / Figure 4).

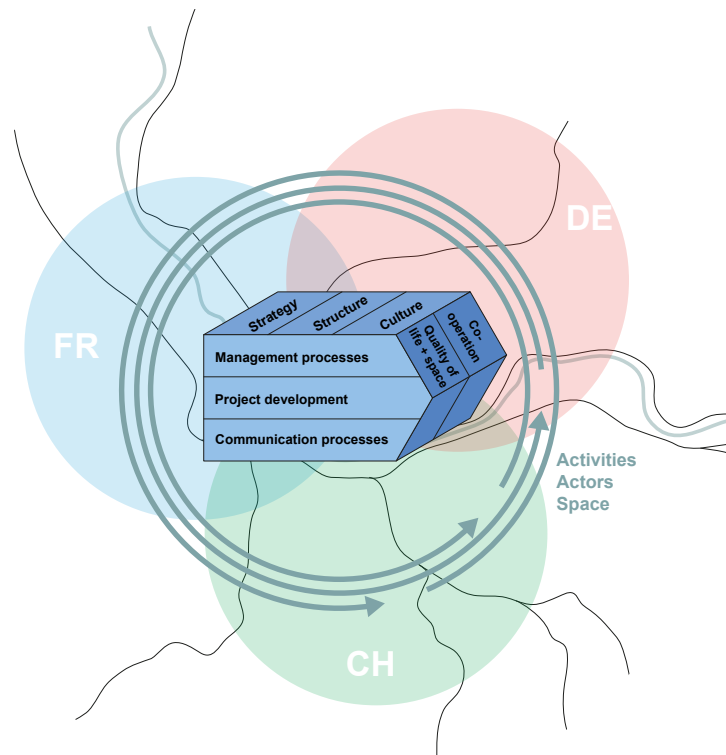

Figure 4: Basic understanding of IBA Basel as trinational development process inspired by the St. Gall Management Model (Source: Author, inspired by Rüegg-Stürm and Grand, 2002)

IBA works as input in trinational regional development and can be identified in the interrelation of structure and process. IBA takes effect through its structuring factors: (1) strategy, (2) structure, (3) culture. Overarching objectives of IBA – such as project-based cross-border regional development – are formulated and pursued to

enhance the development capacity of trilateral space. The strategy provides information about spatial topics and concerns, forms of communication and cooperation of actors, as well as the estimated added value to the quality of life. It informs about the design of planning and development processes. Through IBA, structures and rules are established to achieve the objectives defined in the strategy. These include approaches to link actors across borders in order to trigger change in jointly handling and managing spatial planning and development in the trilateral region. IBA creates a new culture of cooperation and provides a stimulus for new planning culture in three states and their associated regions and communities. IBA promotes processes to increase quality and excellence of projects. Therefore, the quality of equal communication and cooperation between various actors plays an important role. The culture of cooperation disseminates beyond IBA across trilateral space.

In addition to the structuring factors, IBA takes effect through processes. On the level of management processes, IBA strengthens coordination of important committees and decision-makers in politics, of administration, as well as of important private-sector and civic actors. The implemented coordination, consultations and presentations help to identify common goals and to match programs and action. In doing so, the motivation and legitimation of the IBA process are continuously consolidated and developed. Through project development, IBA participates in specific plans and implementations. The projects are the operative core of IBA Basel. These projects are facilitated through IBA in content-related, personnel and financial matters. IBA provides advice, introduces trilateral knowledge, links actors around projects and embeds local and regional projects in a trilateral context. The processes of communication of IBA promotes projects and management through public relations and internal networking. IBA accomplishes formats and opportunities for communication that go beyond the possibilities of local actors. The three structuring factors of IBA processes and structures are in complex interaction with each other. They further develop during the 10 years of time. The processes of planning and development around IBA projects are the core of the operative activities of IBA Basel. Nevertheless, IBA projects should not be considered insolated, yet embedded in strategy, structure and culture, as well as management and communication processes of IBA Basel.

2.3 Levels of impact of IBA Basel and research questions

Until today IBA Basel covers a process that becomes visible, on the one hand, by development on lived space, and on the other hand, by enhanced cross-border cooperation with intensified planning activity. The impact of IBA Basel on the improvement of trilateral quality of life, can thus be visualized on three levels of impact: the networking of actors, the planning activities and projects, and the trilateral quality of space and life (Figure 5).

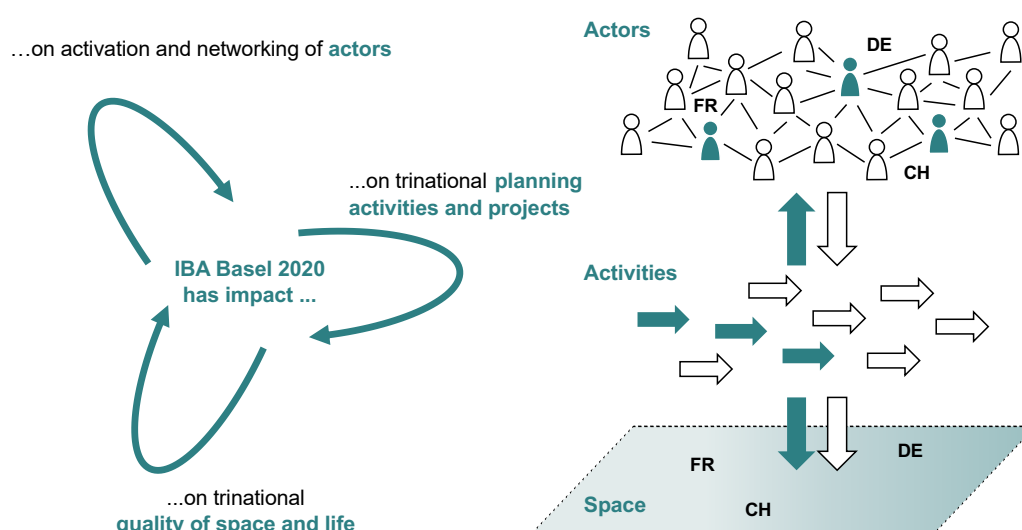

Figure 5: Three interlinked levels of impact of IBA Basel: Activities, actors, space (Source: Author)

The levels of impact are interdependent in their operational progress and build on each other's structure. They profoundly influence and affect each other's outcome in regional planning and design. Although these levels are substantially interlinked throughout the process of each IBA-project, they are basically separated in the design of the research to comprehensively identify the impact on each level. Accordingly, in the course of structuring a research design to measure the impact of trination cooperation and projects of IBA Basel, we have developed hypotheses and research questions for each level of impact. The three hypotheses and corresponding research questions outline three complementary perspectives for reflecting on the impact of the IBA process.

a) Activation and networking of actors

In a period of 10 years, the IBA process brings together various actors of the trination region from politics, public administration, the private sector and civil society. The networking among actors, the activation of new networks and the facilitation of consisting cooperation are the basis for continued impact of IBA beyond the year 2020.

Research question: How does IBA Basel – in its role as a regional development process through projects – contribute to the activation and networking of actors in the trination agglomeration?

b) Planning activities and projects

IBA projects, with their preliminary guidance and planning, complement other ongoing planning activities, programs and projects. They enhance them or even initiate new plans. Thereby IBA operates through own projects, yet the impact of IBA is also determined by the role of projects in the trination landscape of planning and projects.

Research question: How does IBA impact other planning activities in the region? How are IBA projects interlinked with other planning activities in the trination space?

c) Trination quality of space and life

Along with the IBA projects and their embedding in the landscape of trination planning and projects, involved and affected actors link their concepts and expectations for the transformation of trination space, and thus for the trination quality of life. IBA effectuates new spatial qualities in the context of trination planning and projects, which can be measured ex-ante from the perspective of participating actors. IBA will become tangible for the users of space, if the trination quality of life will be enhanced noticeably.

Research questions: What kind of concepts of enhanced quality of space and life in the trination agglomeration are linked by involved actors with activities and projects of IBA Basel? Which project contribution in the landscape of trination planning and projects is provided by IBA for the enhancement of quality of space and life in the trination agglomeration?

The three hypotheses and corresponding research questions are closely linked to our heuristic model. On this basis we have operationalize the questions in order to assess the impact of the IBA Basel process. Thus, in the following section, we will introduce our systematic approach to collect data from the perspective of participating actors.

3. Development of a method to measure the impact of trination cooperation and projects

In this section, we introduce our methodical approach to assess the impact and evaluate the process of an IBA. Building on the outlined conceptual frame, the leading methodological question for the research project is the question of how empirical access can be gained on input and impact of IBA Basel. The research design is based

on the underlying concept that impact can be assessed, firstly, by the starting point of projects, and secondly, by the perception of participating actors. We suggest these two central starting points for the empirical work.

3.1 IBA projects as starting point of the impact assessment

The impact is assessed on the basis of IBA projects as the operative core of IBA Basel. The projects ensure political and public legitimation for the whole process through tangible output. It becomes visible that IBA is partly development of planning principles and concepts, it is making and doing. We have developed an action mode for IBA projects and their planning processes to be able to comprehend the underlying dependencies (Figure 6). The figure illustrates how (IBA) projects are influenced by the facilitation of IBA, a network of actors and finally other planning activities and projects. At best, planning activities and projects initiate and influence each other and are visualized on ground in tangible results.

This conceptual model highlights the hypothetical impact of IBA in the modes of operation within its projects. From this perspective, the contribution to existing and new projects and their impact on planning activities around projects can be surveyed. The resultant further planning activities, the activation and networking of actors and the anticipated impact on trinalational quality of space and life can be assessed. These levels are measured and evaluated for all projects. Besides the synopsis of activities, actors and space, statements can be made for single projects.

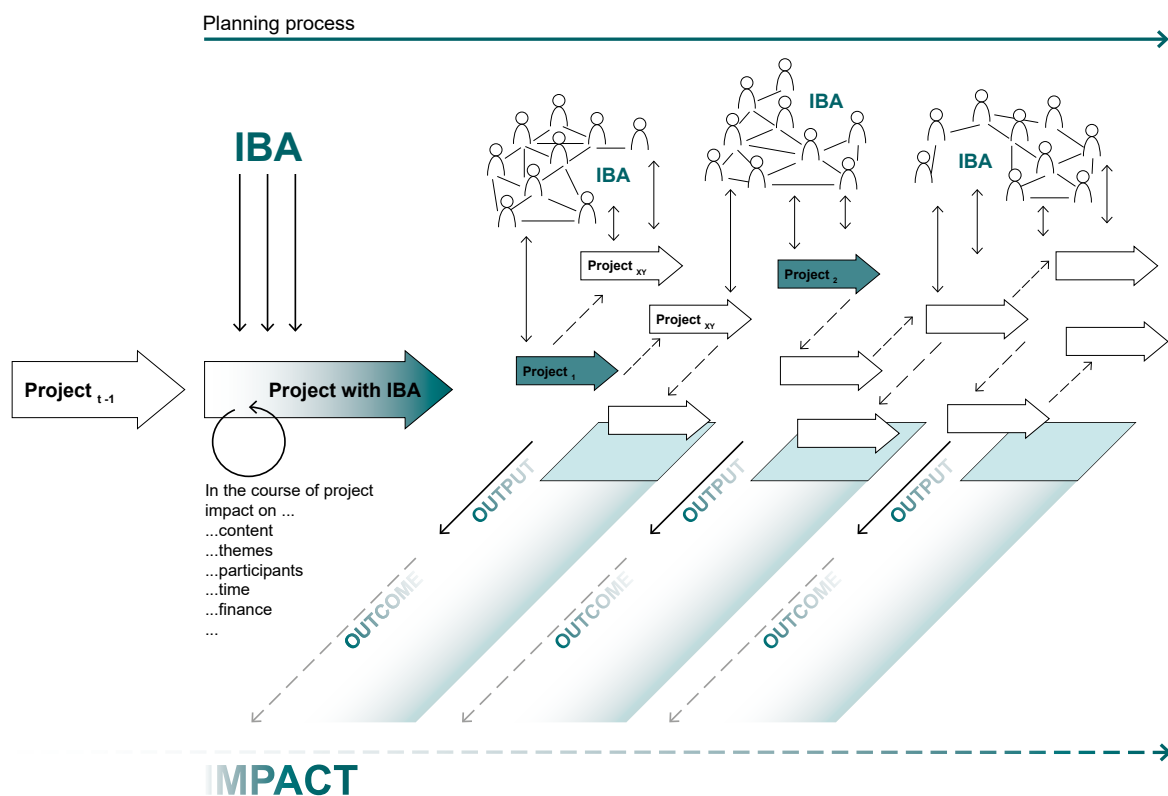

Figure 6: Assessing the impact of IBA Basel based on the action mode of IBA projects (Source: Author)

3.2 Assessing projects through the perception of participating actors

The second starting point covers the perception of participating actors on IBA projects (Figure 7). Input and impact of IBA on the individual IBA projects are assessed through perception, perspective and estimation of participating actors. An online survey for participating actors creates a consistent data base for quantitative research. The intermediate results of the survey will be discussed in focus group workshops with involved actors. Thereby,

actors are encouraged to complete the common reflection and, at the same time, they are activated for the coming exhibition year. Other than that, a reconstruction and assessment of the process and impact of IBA projects would not have been feasible in a similar time frame. We set emphasis on a process-related evaluation considering and including participating actors.

Actors around project

Multitude of actors perspectives on project

1. Actors vary in project
2. Kind of participation varies in project

Actors appear and disappear, are not stable in time

Figure 7: Assessing IBA projects through the perception of participating actors (Source: Author)

The modes of operation, which are originating in the outlined starting points, significantly underline the structure and process that is embedded in the IBA Basel period. We have sketched a starting point, the acquisition by IBA and the future course with its possible outputs and outcomes (Figure 6). The before mentioned impact levels of IBA – actors, activities and space, helped to accomplish the actor-related approach for the assessment of impact (cf. Figure 5). IBA projects and participating actors are the focal points on which we have built up the core of empirical data collection through a mixed-method approach.

3.3 Mix of methods

The research design for the impact assessment of IBA Basel is based on a mixed-method approach that includes an online survey, qualitative interviews and focus group discussions. The data collection will provide scientific foundation, which will be integrated in the final exhibition and will set up part of the exhibition's content. The online survey was conducted among participating actors of (selected) IBA projects. The evaluation of results is further supported by interviews and focus groups. These methods can cover gaps in the research and, at the same time, they provide the opportunity to foster awareness among actors for future challenges in the post IBA period. In the following, we outline the multiple steps of the empirical study – first steps, that have been taken so far, and next steps for the following phase of research.

The IBA laboratory:

Very first insights into IBA projects have been gained through a master course. This format offered students an IBA laboratory to research on single case studies (IBA projects) and go through a joint reflection of these projects. In doing so, students explored the added value and impact of IBA Basel from the perspective of their projects. They travelled to Basel to talk to participating actors and learn about (internal and external) processes of IBA

Basel at first hand. In comparing the projects, we received an impression of the broad range and individuality of IBA projects and their capacity to achieve output, outcome and impact in the IBA process.

Online survey of participating actors:

The online survey of participating actors is based on the previously mentioned structure, which is inherent in the IBA process. Actors were invited to answer a set of predefined questions for selected or multiple IBA projects. Their involvement in several projects, planning activities and cooperation was inquired to learn about networks in the IBA project landscape. Participants were asked to estimate their individual role, as well as the role and contribution of IBA Basel, in the course of the project. They further were able to evaluate the complexity of the project and its general achievements. Additionally, in accordance to the three impact levels of IBA Basel, participating actors had the opportunity to evaluate the project's contribution to the trination quality of space and life. They were asked to identify important and new actors for (trination) cooperation in the selected IBA project and to indicate previous, parallel and further planning activities around the project.

The analysis of data from the online survey will enable us to identify networks of actors, to map related projects and activities, and to sketch anticipated change of trination quality of space and life. The connections, intersections and interrelation of these levels enable us to indicate the impact of IBA.

Focus group workshops:

The focus groups build the intersection between the data collection and evaluation. They will deliver new and consolidated knowledge and enable us to validate preliminary findings. The focus group workshops will be conducted in three divergent constellations: the internal sight, the external sight and the fore sight. The internal sight will be composed of operational IBA makers, who substantially sustained the IBA Basel process. The external sight will assemble a selection of experts, partners and peers to foster the perception on IBA as the non-formal planning instrument. The foresight group will come together to illuminate future prospects and challenges to develop ideas inspired by trends of the IBA region.

The aim of the workshops is to reflect on findings of the online survey. We presuppose that the discussions will enable us to obtain an in-depth understanding for preliminary findings and, at the same time, enable us to gain clarification to validate the latter. From this perspective we will be able to draw further conclusions for the input to the final exhibition. We can use meaningful contents derived from the discussions in the focus groups to underline coherences of the IBA Basel process. Moreover, the reflexive focus group discussions could deliver conclusions and impulses for initiate further development in the post IBA period.

Qualitative interviews:

The qualitative interviews with selected participating actors will be implemented during the phase of the focus group workshops. The aim is to close research gaps, which presumably emerge in the analysis of results of the online survey. The interviews, if conducted with thoroughly selected partners, will deliver reliable contents for filling missing information and missing links to maintain a coherent picture for the evaluation of the IBA process.

The multi-step empirical study for the impact assessment of IBA Basel is still in process. The first step was the IBA laboratory with students, which was finished early this year. The second step was the online survey with participating actors, that was recently closed for evaluation. The preliminary findings of these steps, can lead us to valuable insight for further shaping the focus group workshops and designing the guided interviews. Both will be conducted in autumn 2019. In the following section, we give insights into results of the first methodological step of assessing IBA Basel.

4. Preliminary Results: Learning from IBA Basel projects

We can draw preliminary results from the IBA laboratory, where master students carried out in-depth analysis and reflection on selected IBA projects. The research highlighted, that from its office, IBA Basel offers a common label and supports projects in various roles and forms: through consulting, networking, coordination and communication. The agency and the label IBA are able to make different contributions and to influence the content and procedure of IBA projects. What effect does IBA have on the content of a project and its progress? 13 students of RWTH Aachen University investigated this question in the research laboratory for selected IBA projects. The students derived metaphors from their findings and visualized the contribution and impact of IBA Basel within projects in 3D planning models. Although, the models express different metaphors for individual projects, they deal with similar contributions of IBA in several projects. In the following we have identified three main aspects that can be described exemplary on selected IBA projects.

4.1 IBA networks, projects and participating actors

IBA projects are processes in which various actors from different spheres such as politics, administration, private sector, civil society work together. IBA accompanies its projects from their office with project managers, who act as contact persons for all actors. Where necessary, new contacts – including cross-border relations – are established to network with stakeholders. This is exemplary in the projects IBA KIT and 3Land:

Figure 8: Planning models for the projects IBA KIT and 3Land (IBA KIT: Viktoriya Nikolova, Christiane Schubert; 3Land: Melanie Heinz, Jeremias Klug).

IBA KIT (Figure 8, left) is a tool to activate unutilized public space in the cross-border region. Containers serve as basic modules. They are used in diverse ways to increase quality of life in selected areas. The containers are adapted to its individual function and location – some of them are permanently installed, others are constantly changing locations. Thanks to IBA Basel the mainly local functioning ‘KITS’ are bundled into an overall concept. By strengthening communication and exchange between involved actors, IBA Basel initiates a mutual learning process, which in turn, results in high quality projects. The students’ work highlights this contribution of IBA as a ‘guiding track’ on which actors can move between the projects.

In the case of 3Land (Figure 8, right), students identified a bundling of several projects and actors through IBA. The cross-border district with jobs and housing for 20.000 people is build along the river Rhine in the border triangle between Basel (CH), Huningue (F) and Weil am Rhein (D) on an area of more than 400ha (IBA Basel b, n.d.). Many smaller projects are part of the on-site development and a corresponding number of actors are involved. In this project, too, IBA's contribution is bringing activities and actors together – with the aim of strengthening networking, communication and cooperation.

In the process of 10 years of IBA Basel, it is valuable to develop and apply procedures that initiate and activate the described networking. Especially the IBA KIT can be understood as supportive method and tool for the whole process. It differs from other projects due to its flexibility and adaptability.

4.2 IBA functions as stabilizer in projects and processes

IBA Basel influences the timelines of projects, since it supports projects in coping with challenges and difficulties. The two examples in need for such contribution are the projects motoco and Zoom:

Figure 9: Planning models for the projects motoco und Zoom (motoco: Camille Leclerc, Madita Fislake; Zoom: Friederike Bobenhausen, Denise Knauer)

Motoco is a creative and cultural project that started in the old spinning mill of the DMC district in Mulhouse (F) in 2013. By converting a factory into an open idea laboratory for artists and creatives, motoco is experimenting with new working models (IBA Basel c, n.d.). The planning and implementation process for motoco is characterized by the network and cooperation of various actors. The students' model represents the process as a tower from the bottom up with the involved actors as colored 'building block' (Figure 9, left). IBA Basel (blue) forms an essential module in this tower with a stabilizing effect in the procedural structure and network of actors.

Zoom (Figure 9, right) set itself the target of mapping the whole area of IBA Basel from the point of view of youngsters and children by 2020. Therefore, young people were asked to draw pieces of the map, that should be digitalized and afterwards become a puzzle. The resulting plan of the region should reflect the needs of these stakeholders (IBA Basel d, n.d.). "Without the IBA, the Zoom project would not have taken place like this", the students learned in an interview during their research project. In reflection, they understand IBA Basel as a framework: Without the various 'ingredients' of the project and process, such as idea, actors, commitment and know-how, organization, planning and financing, the map basis or further materials would fall apart.

We can conclude that IBA helps to initiate and motivate to start and continue projects that are full of risk or free from any bias.

4.3 IBA provides orientation for projects and their progress

IBA advises, coordinates and supports projects with its expertise. In addition, the labeling process with several criteria developed by IBA Basel defines standards of content for IBA projects and their milestones in the timeline. This can lead to changes in the content and orientation of projects, as it can be seen in Polyfeld Muttentz and Neue Mitte Grenzach:

Figure 10: Planning models for the projects Polyfeld MuttENZ and Neue Mitte Grenzach (Polyfeld MuttENZ: Carina Engler, Chiara Erhardt; Neue Mitte Grenzach: Lina Wahdan).

In MuttENZ in a district of 34ha, which is nowadays industrially used – the Polyfeld MuttENZ, a sustainable and mixed district is to be built. During the IBA Basel process it was tested, which measures of social sustainability could be implemented in an urban planning project. For this purpose, traditional urban planning was combined with bottom-up participation processes. Due to the labeling process IBA specified criteria referring to content and milestones of the process. Thus, in this project – as well as in other labeled projects – changes in content were initiated and project developments were influenced by IBA. The students' model expresses a marble run in which the marble runs through the multi-level process of the project, relating to various stages of consulting and qualification by IBA. IBA Basel is represented as a steering element that triggered another direction for the Polyfeld MuttENZ at the time of nomination (Figure 10, left).

The metaphor 'coordinate system' illustrates that IBA indicates directions (Figure 10, right). It refers to the project 'Neue Mitte Grenzach' – the revitalization of the town center of Grenzach Wyhlen (D). A redevelopment area near the station will be developed in order to enrich the existing town center with businesses, residential use and public spaces. New mobility connections structure the area and help to connect the old town center with the station and the river Rhine. The inclusion of the station and riverbank into the planning concept made it obvious that the project became part of the project groups Aktive Bahnhöfe and Rheinliebe. IBA Basel served as coordinator and provided clarification and orientation regarding definition, content and progression of the project.

This shows that IBA Basel helps projects to clarify contents and to set structures in complex planning and development processes.

5. Outlook: Perspectives for the post IBA period

Although the research project is currently ongoing – in particular the evaluation and interpretation of the online survey have not been completed yet, we can already draw first conclusions and learn for the post IBA period.

As delineated in this paper, the transformation of an entire region was initiated by the 10-year process of IBA Basel 2020. It should be an indisputable fact, that it is worthwhile to continue this prospering process in order to further develop the region and thereby increase its quality of life and space. As mentioned at the beginning, the attempt to push the IBA process far beyond 2020 has to start as soon as possible. Therefore, on the one hand, the achievements of the process should become visible and be displayed in the final exhibition. On the other hand, the development and growing-together of the region, with its improved qualities, should become visible for its residents and users in everyday life. This results in the following future tasks.

Ensure the quality of cross-border regional development through a follow-up institution

There is a need for a successor institution that continues the core tasks of the IBA office. Among other things, these include: existing and new formed networks of actors that maintain intensified cross-border exchange; further elaboration of tools in order to support the regional development – for instance the IBA KIT; ongoing support of IBA projects until their completion; formation of additional project groups – to develop or strengthen fields of action and topics that respond to future trends in regional development.

Proceed the pool of experiences of the IBA process

IBA gained experiences during the 10-years process from which a follow-up institution can benefit in the post IBA period. IBA has achieved skills, not only in regional development and project management, but also in soft dimensions such as multilateral networking, trust building and cross-border knowledge sharing. It would make sense if this pool of experience was captured to be passed on through a conscious change management.

Bring transformation to life

Exhibiting the different IBA projects in the Vitra Design Museum in 2020 is not sufficient enough – the region needs to become perceptible for its users. IBA is considering how the development and growing-together of the region with its improved qualities can be experienced by the public, since some of the IBA projects are still in the development process and will not become finished before 2020. In this way, a challenge for the post IBA period is to bring transformation to life – unfinished IBA projects should be supported, pushed on and made perceptible during their realization process.

Bring the regional scale to the general public

Until today, IBA Basel is known in the professional sphere, yet general public and media have less knowledge about IBA. This is one of the reasons, why IBA wants to address users in the year of presentation and in the post IBA period. There is a need for a media and communication concept beyond the final exhibition and the year of presentation, which also goes beyond the presentation of individual projects. Through this strategy, target groups should be clearly addressed and invited to experience the region as a whole. An ambitious and yet desirable result would be, if awareness of a 'home region' emerged.

The research project is not finished yet. The next step is to generate results from the quantitative online survey. The results will then be reflected in order to gain a deeper understanding of a) the surpluses of the IBA process and b) of the improvements made commonly in cross-border regional development. Three goals are pursued for further work on the impact assessment of IBA Basel:

Firstly, a scientific basis for presenting results and impact of IBA Basel in the final exhibition needs to be created. Secondly, participating actors of the IBA process need to be involved in the common reflection and, moreover, need to be activated for the year of exhibition. Thirdly, motivation to continue the trinational communication and cooperation process in the post IBA period needs to be increased on the basis of research results.

Acknowledgements

We would like to thank the IBA Basel office for the trustful and constructive cooperation. We thank all actors involved in the IBA Basel process, who supported the research project so far – and thus the preparation of the year of presentation, by participating in the online survey. Last but not least, we thank the students of RWTH Aachen University for their engaged and creative work in the research laboratory.

Abstract: Urban Design and Planning worldwide have long been criticized for their lack of meaningful public consultation and participation in the process of shaping our built environment. Currently, the existing practices of consultation and participation are within the confines of council meetings, complex form filling and survey reports that often carry little weight towards the decisions made by the planning authorities; the latter are increasingly seeking for ways to encourage meaningful public participation in urban development decisions. This paper presents a systematic literature review on sustainable urban governance vis-a-vis participatory planning, in an effort to consolidate, evaluate and critique the various approaches on involving the public in decision-making process in relation to urban form in general and public space in particular. The literature/case studies presented are referenced across a scale of degrees of participation, referring to a range of influence that participants have in the decision-making. In its two extremes it can be viewed as no participation, where designers make assumptions of users' needs and requirements, and full participation, based on user-defined criteria of quality. The evaluation of many participatory research practices is somewhere in between the two extremes, focusing more on design with the users. However, the given theoretical process, might provide an insufficient degree of realism that designers need to cope with, due to time and budget constraints. If it is to remain grounded to the practice of design, literature should be able to cope with barriers, and seek understanding beyond its conceptual approaches.

Keywords: participatory planning; urban development; sustainable urban governance; public participation

Introduction

“Participation is a general concept covering different forms of decision-making by a number of involved groups” (Wulz, 1986). Participatory design is based on five fundamental points. First, *politics* in terms of people who are affected by a decision should have an opportunity to influence it; second, *people* in terms of being experts of their lives and having an influential role in design; third, *context* in terms of situations; fourth, *methods* as being the means of users to gain influence; and fifth, *product* in terms of the final goal of participatory design. The empowering quality of life that participatory design is meant to offer is hidden within that final goal (Halskov and Brodersen Hansen, 2014). Throughout the literature, participatory planning can be organized through three main themes

consisting of varying approaches: 1) motives of deciding to engage in participatory design, 2) degrees of participation that may occur, and 3) types of participants who get involved in terms of networks and scale.

In the 1960s and 1970s, the primary motivation of participatory design was linked to “the democratization of work life” (Schuler and Namioka, 1993, p. 251). It emerges as a reaction to the “mismanagement of the physical environment” (Sanoff, 2006, p. 140) and as an attempt to improve the quality of design and planning. Today the democratic and pragmatic efforts of participatory design seem to be shifting perspectives (Sanoff, 2006). Sanders et al. (Sanders, Brandt and Binder, 2010) argue that before someone attempts to customize participatory tools and techniques, they should firstly be able to understand the purpose and context of participation. Even though participatory literature offers a plethora of approaches, the core motivations of participatory researchers and practitioners have been identified and clustered in the following three areas: a) ethics (democracy), b) curiosity (theory), and c) economy (pragmatic) (Bergvall-Kareborn and Stahlbrost, 2009).

The degree of participation refers to a range of influence that participants have in the decision-making resulting to the final product. The level of participation that is required is a matter of ‘subjective intention’ (Andersen *et al.*, 2015). In its two extremes it can be viewed as no participation, where designers make assumptions of users’ needs and requirements, and full participation, based on user-defined criteria of quality (Bergvall-Kareborn and Stahlbrost, 2009). The degree of participation can also be described as indirect or direct (Ives and Olson, 1984). In reality, the evaluation of many participatory research practices is somewhere in between the two extremes, focusing more on design with the users (Bergvall-Kareborn and Stahlbrost, 2009). However, the given theoretical process might provide an insufficient degree of realism that designers need to cope with, due to time and budget constraints. If it is to remain grounded to the practice of design, literature should be able to cope with barriers, and seek understanding beyond its conceptual approaches.

In order to address the issue of balancing theoretical proposals with the constraints and practicalities of design, a systematic review of case studies of participatory design projects was undertaken with the aim of responding to pressing questions regarding criteria to establish how effective participation is implemented and evaluated in real-life contexts. Specifically, this paper addresses and discusses what the state-of-art offers to respond to the following questions:

- How much participation is enough?
- How much commitment is reasonable?
- How can the participants be engaged in the process in the long run of participatory design?
- Should the reasons of participation be ethical or financial?
- How can multiple views and incentives be coordinated in participatory dialogues?

The criteria of what qualifies a participant is considerably broad (Schuler and Namioka, 1993). Usually there are many types of participants taking the form of individuals or groups, interacting either in face-to-face sessions or in online environments (Sanders, Brandt and Binder, 2010). The literature indicates that the types of participant involved are decided based on the scale of the project, the scope and the context in relation to place and time. However, it can be argued that the way participants are perceived by researchers is segmented (designers and participants as separate groups) rather than a collective (designers and participants as part of the same group). This raises questions regarding how different participants interact with each other and how their views impact on decision-making processes. Recent literature suggests that participants are not stand-alone subjects, but part of social

networks (Andersen *et al.*, 2015). Viewing participants as networks (designers, users, stakeholders together), who are always partially integrated in the process and have the ability to cluster and interact, might provide the potential to displace the research focus and shift the participation paradigm.

This paper presents initial findings from part of a systematic review of literature on participatory planning which is being undertaken for the project Sustainable Urban Governance through Augmented Reality (SUGAR). The project aims to develop innovative best-practice protocols and guidelines on sustainable urban governance and, specifically, public participation through augmented reality. The research presented within the scope of this paper focuses on participatory planning approaches to decision-making for the design of public spaces. As this research aims to address effective participation in real-life design contexts, this part of the review focused on case studies. It also intentionally excluded interventions using solely or mostly ICT and augmented reality (though case studies comprising a level of technology use were considered) – this is a core element of SUGAR and the related literature review on these aspects is to be published elsewhere.

The methodology to carry out the systematic review and the analysis of the selected studies is described in the next sections. The findings from the studies on the effectiveness of various methodologies are presented and key issues are discussed according to themes emerged from text analysis of the literature. Conclusions are then drawn in relation to the questions we aim to address, summarizing key messages of the state-of-the-art regarding the strength of the current evidence, existing gaps and where future research should focus to support effective participatory planning.

Methodology for systematic review

The literature search was performed through the following databases: Web of Science, ProQuest, Social Science Research Network, RIBA Library Catalog, JSTOR, and EBSCO Art & Architecture Complete. Both peer-reviewed and non peer-reviewed articles were searched for through the search terms ‘participatory design’ and ‘participatory planning’. Results were filtered by selecting the relevant subjects/topics pertaining to the field of the built environment. These varied substantially between databases and ranged from architecture, urban studies, cities and development studies to social sciences, public administration, planning and sustainability. Only English-language articles were included in the search, which yielded well over 300 articles. A small number of articles were not accessible and once duplicates were excluded, a manual selection was done to identify the most relevant articles based on title of the article and topic of the journal or conference proceedings in which the article was published: attention was given to selecting articles which related to the urban environment, included case studies and were not explicitly focused on technology. A final set of 85 articles was selected for review; at the time of writing this paper 35 articles (30 peer-reviewed and 5 not peer-reviewed) had been reviewed, most of them case studies and a few reporting reviews of literature and methods of participatory planning.

The articles were analyzed using QSR’s NVivo 12 Pro software for qualitative data analysis. The articles were read by a single researcher and relevant text coded according to emerging themes. As the subjects of participatory planning broadly fall within the field of (applied) social sciences and the great majority of articles’ methodologies fell within the qualitative type, it was considered not appropriate to perform a statistical meta-analysis. As suggested by Davis *et al.* (2014) for certain research questions, meta-analysis is not necessarily the best tool, if suitable and acceptable evidence comes through research strategies which do not include experimental research or randomized samples. In these cases traditional narrative review, best-evidence, thematic or interpretive syntheses enable a broad review and provide the basis to answer specific questions. It was therefore decided that the most appropriate

method for the analysis of this type of primary research was ‘thematic synthesis’, a type of thematic analysis of primary research adapted for use in systematic reviews (Thomas and Harden, 2008). Accordingly, all selected studies were entered verbatim into NVivo software. The first stage of the synthesis was to identify the findings of primary studies by extracting key concepts from the full text – it was sometimes difficult to identify these and summaries of findings as qualitative research is characterized by varied reporting styles where findings can be located in different parts of the text and labelled in different ways. In some cases, additionally to ‘findings’, ‘results’, ‘discussion’ and ‘conclusions’, findings were also placed within the description of the case studies or the activities undertaken. Text describing the case studies was also coded for reference purposes, text from literature reviews and syntheses of specific topics reporting other primary research was also coded to provide additional evidence material. Furthermore, text referring to the methodologies used for participatory activities was also coded in order to collate information about the amount and types of available methods and tools.

The second stage of synthesis involved comparing nodes of codes in order to assess how much overlap there was between different themes, running word frequency queries of codes in order to identify issues of particular relevance within themes and display these as word clouds to visualize them for reporting (queries were limited to 50 words with a minimum length of 4 characters). The frequencies were compared between codes to assess if similar issues were relevant to more than one theme; when the most recurring word featured in more than one theme, these were grouped together to generate word clouds. By combining the results of these analyses it was possible to develop descriptive themes comprising the evidence related to concepts directly addressed by the primary studies: the benefit of these is that they focus the evidence on one particular concept which can provide a framework when planning and implementing participatory initiatives.

The final stage was that of making inferences to answer the review questions based on the evidence collated through the search, coded through text analysis and reported through descriptive themes. As with all synthesis of qualitative analysis, this is the most difficult and controversial stage, since it is dependent on judgment and logical reasoning of the researcher. Within the scope of this study it was not possible to use more than one reviewer to make inferences independently in order to cross-check and validate this – it is a limitation of this study and the authors aim to address this in the next phase of Sugar’s review process.

Findings

The first and foremost finding at this stage of the review is that while globally there has been a paradigm shift toward participatory planning, there is still a scarcity of detailed reports and critical assessment of what constitutes effective participation (Andersen *et al.*, 2015) and no consensus as to how to achieve inclusivity and participants’ sense of ownership over outcomes (Leyden *et al.*, 2017). The concept of co-creation within the field of participatory design has been used for decades, but its positive impacts are not necessarily self-evident (Lundström, Savolainen and Kostianen, 2016) and it is not always clear what and how much community groups, especially in contexts of low resources and high inequalities, can gain from participatory processes (Refstie and Brun, 2016; van Holstein, 2018).

The definition of ‘participatory development’ by the World Bank’s Learning Group on Participatory Development – “a process through which stakeholders influence and share control over development initiatives and the decisions and resources which affect them” – is sometimes used as a benchmark for ensuring and assessing participation in interventions (Ngah and Zulkifli, 2014). Many other definitions exist which focus on somewhat different aspects of the process: the inclusion of all levels of society in

decision-making (Bonilla, 2009), the continuum of activity in communicating and engaging with the public (Kotus, 2013), the openness and multiplicity of the process (Manzini and Rizzo, 2011), its and its transformative and innovation potential (Manzini and Rizzo, 2011; Refstie and Brun, 2016). Existing definitions indicate that participation per se, the process and outcomes are the core features of successful participation; although inclusivity is given consideration, the extent and level of participation are not given much attention. The exception to this can be found in a specific theoretical framework to participation based on Actor-Network Theory. This does concern itself with ‘practical’ aspects, but in order to directly argue that how many, who, how and how often participants are involved is irrelevant because participation is a matter of concern rather than a matter of fact – as such, participants act directly and indirectly as components of networks and participation occurs aside of designate activities and is an existent aspect of the whole process: no form of participation is ‘superior’ to others, therefore there is no gold standard for it (Andersen *et al.*, 2015).

Acknowledging these premises, the authors of the present paper aim to give an overview of existing methods and of the evidence relating to key issues around participation. There are three main types of participatory planning: formal (or bureaucratic) participation, action research, and community-led or community-driven participation. Formal participation is led and implemented by state agencies or local authorities, normally as a legal requirement of planning legislation; it tends to involve classic methods of consultation such as surveys, meetings, hearings and sometimes workshops. This type of participation is the one that is most subject to criticisms of ‘tokenism’ – the undertaking of participatory activities purely to tick off legislative requirements. Such criticisms tend to be frequent when the public’s suggestions are not taken up (Zhou, 2018), are dismissed as uninformed (Al-Nammari, 2013) or market powers ultimately direct decision-making (Turan, 2018). Action research is usually led by academic institutions implementing interventions with the aim of simultaneously pursuing impact, change or innovation through participatory practice and producing research findings to inform the project and to develop understanding of the process (Sanoff, 2012). Community-driven participation is, as the term implies, led by the community itself, embodied in more or less formal organizations taking up an issue or devising an intervention through campaigning initiatives or practical projects which may, at some point, require contact and involvement of the authorities. While these are often deemed as being more inclusive and their informal methods can be highly successful, concerns are also raised as to the true nature of inclusiveness if the groups involved are not representative of the wider community, have specific interest or are not accountable for their actions (Hou and Rios, 2003). While all these types of participatory actions can apply to different scales, from the single, small regeneration or design project to metropolitan strategic plans, local and smaller-scale projects are often the domain of action research and community-led activities. Participation in large-scale and strategic consultative processes are normally still the domain of bureaucratic participation - a notable exception being the activities of REDWatch (Rogers, 2016).

Along with the variety of approaches to participatory planning comes a wider range of methods and even wider set of specific tools. The main methods retrieved from the literature so far are presented here with a brief description and summary how they performed in the case studies reviewed; it is not an exhaustive list of all individual tools discussed in the literature – many studies include and assess a variety of individual classic consultation tools – rather this list highlights methodological strategies which can embed a number of tools.

1. Change by Design (Frediani, 2016). This methodology was used as part of ASF-UK project of informal settlement upgrading in cities in Brazil, Kenya and Ecuador. It involved two-week workshops in each city using audio-video techniques to capture residents’ experiences and aspirations. The author states that that the workshops supported communities to negotiate

alternative solutions and influencing government authorities in engaging with participation and supporting upgrading schemes. They conclude that this method is most successful at mediating diverse interests (rather than conflict resolution) and at fostering learning and action towards urban social justice.

2. Charrette (Lundström, Savolainen and Kostianen, 2016). This methodology is a collaborative planning and negotiation process; in the case study reviewed, it was used for the renovation and conversion of a university campus lunch restaurant redesigned to become a learning space. Charrette workshops are highly structured and facilitated involving drawing, creative and hands-on tasks. The authors conclude that this method is successful in embedding user perspective in design and provided a positive impact on the resulting premises, but not every part of the project was successful as some of the objectives for the new design were not achieved.
3. Informal Activities (Hou and Kinoshita, 2007). Rather than a methodological strategy, this study looked at a set of informal participatory activities that took place in Kogane, Japan, to assess their success in comparison to formal processes which took place in Seattle, USA. The authors acknowledge that many of the informal techniques developed by communities, such as walking tours, design games and social events, have already been incorporated into formal processes. Nevertheless, they are worth of attention because they show to help overcome limitations of formal participation and negotiate difference. Animated interactions, experiential learning and spontaneity were the key factors in developing trust between stakeholders.
4. Iterative and Recursive Prototyping (Erixon Aalto, Marcus and Torsvall, 2018). This methodology was applied in the Albano Resilient Campus Project in Stockholm in order to produce knowledge and operationalize concepts of resilience and ecosystem services. The method involves a recurrent series of workshops with design sessions in between; the design outputs from each session are explored through generative matrix models to provide information of the potential performance on the proposed design and thus input into the next iteration of prototyping. Comprehensive narratives were used throughout the design process to offer alternative views of socio-ecological processes. The authors conclude that the process is effective in introducing communication and feedback, generating questions and re-examining problems. While it did not necessarily provide solutions, it enables actors to identify points of conflict and convergence, but can sometimes function in an excluding manner for actors entering the process in later stages.
5. Local Economic Development (Majale, 2008; Bonilla, 2009). LED is a process in which local people from different sectors work together to stimulate commercial activity to achieve a sustainable economy. It is characterized by the development of long-term public-private partnerships, the fostering of social networks, the mobilization of endogenous resources and a focus on a defined territory. In the case study reviewed of slum upgrading in Kitale, Kenya (Majale, 2008), it was shown that labor-based methods presented many advantages to participation in slum upgrading which can support sustainability through job creation and income generation. The author, however, points out that for such methods to have long-term impact, they must be accompanied by other activities such as training and capacity building. In a second case study of the Cordoba-Orizaba region, Mexico (Bonilla, 2009), the method was found effective in achieving consensus among stakeholders and agree strategic objectives for a common vision for the region. The author, however, points out that in this context, the methodology is subject to uncertainties at implementation stage due to mainstream political and economic culture, which does not legitimate participatory planning.

6. Participatory Rural Appraisal (Halkatti, Purushothaman and Brook, 2003; Sharmin *et al.*, 2013). PRA is an approach for shared learning between local communities and outsiders used to assess resources and skills, identify issues and propose solutions. This method was specifically developed for rural areas, but it has been tested in urban contexts as some of its tools, are applicable to all environments. A benefit of PRA is that it does not require technical knowledge to collect data, as such it can be easily implemented in a variety of contexts. It the uses statistical tools to prioritize problems and identify their causes and effects. In the case study of Hubli-Dharwad (Halkatti, Purushothaman and Brook, 2003), PRA was successful in helping communities define and present issues and develop action plans; it was also used as an evaluation tool to compare the situation before and after intervention. In the case of Monipuripara (Sharmin *et al.*, 2013), it was found effective in fostering understanding between local people and outsiders, as well as easy to implement. However, when proposed solutions could not be implemented by the community itself, success rests with resources and commitment of local authorities and was thus not guaranteed.
7. Personal Construct Theory (Dayaratne, 2016). PCT was used a s framework for developing techniques to understand how people see and value their places. It was applied in housing project in Haputale, Sri Lanka. Within these framework sorting and location tasks were carried out with residents and they were deemed successful in directly informing design, rather than just producing a set of issues or priorities for the architect to take into account, and achieving a closer correspondence between the way people conceptualized their space and the space that was eventually constructed. No shortcomings or difficulties with the methods used are reported in the case study.
8. Role Playing (Valladares, 2017; Turan, 2018). Role playing is a specific tool which was used as part of participatory activities in the neighborhood of Gowanus, NY (Turan, 2018) and in self-help house building and renovation projects in Old Havana, Cuba (Valladares, 2017). It is a tool that is used in a variety of fields and embedded in participatory activities along with other methods. However, it is worth mentioning on its own as the evidence from the Cuban case study highlights this a particularly powerful tool to facilitate engagement, despite the fact that the evidence from the Community Architect Program in Havana displays mixed results with residents from more favorable socio-economic circumstances benefiting more than low-income groups.
9. Scenarios (Celino and Concilio, 2010; Chakraborty, 2011). Structuring scenarios were used to manage participatory activities to develop a long-term plan for the Delta of the Po River in Italy (Celino and Concilio, 2010); these scenarios are meant to evolve together with the decision system and aim at envisioning multiple possible futures rather than converging into a single solution. As these can continually evolve, they provide a good basis for long term engagement and may enable the selection of a preferred scenario over another. However, the authors point out that they may not work in all planning situation as the scenarios might not be under the control of relevant authorities. When scenarios were in used in the Washington Metropolitan region (Chakraborty, 2011) they were found to be valuable in capturing issues for the future and creating awareness and knowledge – they have the potential for both quantitative analysis and feasibility testing, but also for engagement and generation of alternative objectives through qualitative methods. The author points out that the analytical process had limitations because of oversimplifying assumption and limited numbers of indicators, but the outcomes were still successful and provided a foundation to achieve tangible benefits.
10. Urban Living Labs (Puerari *et al.*, 2018). There are several definitions of ULLs, but these are generally understood as combinations of several tools to co-create solutions taking place in real, physical environments. A series of ULLs with different characteristics, aims and locations taking

place in Rotterdam in the Netherlands were evaluated and were found to contribute significantly to production of local knowledge and were effective instruments in bringing different actors together and developing potential solutions to specific issues. However, as ULLs are usually set up with a specific purpose they do tend to be successful for a particular case at the scale at which they were set up to work, but they might not necessarily be transferrable or able to impact on a larger scale or beyond those stakeholders directly involved.

11. Visual Mapping (De Vita, Trillo and Martinez- Perez, 2016). This ‘traditional’ methodology was adapted for use in the case of Belfast by developing a taxonomy of urban elements to capture existing and hidden conflict. This adaptation was thought of also with the potential to support community planning in any rehabilitation project. The authors found that adding the taxonomy to this method refined in such a way that made more effective for used in contested places such as Belfast.
12. Working Group (Al-Nammari, 2013). While WGs are used as a tool in various processes, in the case study reviewed of the Talbiyeh Refugee Camp Improvement Project in Jordan, it was used as the key method: an open forum where visions for improvement were developed and results of activities and interventions discussed. This particular project was fraught with limitations and failed implementations of agreed solutions due to its specific context of power-relations amongst stakeholders. Nevertheless, the author suggests that it can provide a step forward towards democratization of planning practices in contexts where participatory planning is rarely practiced.

Regarding the analysis of key issues in participatory planning, comparative diagrams of codes highlighted specific strong overlaps between themes, which were similar to common word frequencies. Based on these analyses the descriptive themes comprising evidence from related issues are presented below.

Creation: level of participation, level of commitment and reasons for participation

Level of participation in successful participatory projects ranges widely depending on the size and scope of interventions, its aims and objectives and the type of activities planned. Successful activities might have from as little as 20 participants (DiSalvo *et al.*, 2012) to over 100 organizations (Chakraborty, 2011) and over a 1000 attendees to final project events (Manzini and Rizzo, 2011).

Analysis of themes overlap reveals that level of commitment is directly dependent on level of participation, something which is perhaps intuitive as commitment cannot be gained unless participation is achieved first. Evidence shows that a physical and visible space where activities take place is a very strong factor in achieving participation and engagement (Puerari *et al.*, 2018). This does not diminish the potential that ICT tools may have to foster engagement, but the evidence from the reviewed case studies is mixed as to their impact with some showing very little engagement (Kotus, 2013), others a reasonable level of activity (Turan, 2018) and still others being highly successful (Rogers, 2016).

Most studies reveal that they primary and most powerful reason for participation is to develop a solution to a problem that affects them (Manzini and Rizzo, 2011), achieving their goals and aspirations of a better environment (Turan, 2018; van Holstein, 2018) and accessing needed resources (Al-Nammari, 2013). However, certain specific stakeholder have intrinsic economic reasons for participating (Leyden *et al.*, 2017) or may simply have a legal mandate to do so (Halla, 2005). It also has to be noted that while financial incentives were clearly not the main reasons for participation, the lack of such direct incentives may hinder participation, commitment and ownership over the outcome

as well as causing conflict and resentment among participants in contexts of high disadvantage and socio-economic inequalities (van Holstein, 2018).

The word cloud for this theme (figure 1) reveals how the goal of creating something is the key factor in participation; stakeholders, actors, people, groups and communities given the opportunity to be involved in projects, activities, place-making, and social innovation through an appropriate process motivates them to participate and commit to design solutions to critical issues.

Figure 1. Word cloud for codes: level of participation, level of commitment and reasons for participation.

Process: coordination of multiple views, inclusivity, long-term engagement and sustainability

There are two main approaches to coordinating multiple views in participatory planning: that of allowing for multiple perspectives and conflicting interests to coexist, such as in the cases of scenario building or iterative prototyping, or that of trying to achieve common agreed objectives as in the case of LED. Clearly, as the word cloud for this theme reveals (figure 2), process is the key factor in how multiple views are coordinated. Scenarios seems to be effective in developing long-term views rather than addressing pressing needs. However, implementation and long-term engagement more directly relate to commitment on the part of authorities to truly include participants' views in plans and to the success of the events and people's sense of ownership over solutions, than to the methods used for the activities.

Throughout the literature achieving broad participation from the early stages of the project was seen as a key factor in achieving inclusivity and long-term engagement. Using specific strategies to maintain collaboration during all phases of a project, especially when it seems that participants have less to say, was recommended in the experience of some researchers (Lundström, Savolainen and Kostiaainen, 2016). In order to achieve inclusivity certain groups, such as women, youth and the poor should be

analysis of bias and limitations. In light of growing diversity and complexity of urban environments community-led actions often seem to have less limitations than formalized practices, but as previously mentioned these can also come with their biases (Hou and Kinoshita, 2007).

Reports of bias in Western case studies are less frequent, although these do exist (Luck, 2018; Puerari *et al.*, 2018), but as the reviewed literature often does not mention or assess this issue, consideration might be given to the fact that in Western, wealthier contexts assumptions may be made that bias is less frequent and is thus assessed to a lesser extent.

Figure 3. Word cloud for codes: bias and limitations.

Conclusions

As presented in the analysis, turning back to some of the research questions: level of participation, level of commitment and reasons for participation really rest with the creative power of interventions to deliver solutions. This is regardless of the type of participatory action, whether it is bureaucratic, action-based or community-led. Appropriate processes must be developed in order to coordinate multiple views, ensure long-term engagement and sustainability of projects; in order for this to happen inclusivity is key, not just in terms of variety of groups involved in the process, but also with regards to the extent to which their views are taken into serious consideration, embedded in plans and finally implemented. Bias and limitations can be mitigated through active inclusive practices, but strong leadership and political will are the key factors in minimizing bias and reducing limitations (Gedikli, 2009), especially at implementation stage.

Motivation to participate should and most often is related to aspirations, desired outcomes and a variety of social benefits which people, community and groups can gain through activities. These are proven to be the most powerful forces to gain participation, commitment and long-term engagement. Therefore, while financial incentives are not usually a necessity and are unlikely to improve the process and outcome, they should be considered in cases where including disadvantaged populations may be problematic and in contexts of high inequalities.

So far, the literature presented no case studies with a specific focus on public space, but the methods reviewed are applicable to a variety of urban settings and case studies comprise scales which include public spaces. It may be that there is scope for further specific research on public spaces, especially in light of the fact that physical and visible space is a very strong factor in engagement. While we have not yet focused on the issue of how participatory processes are linked to sustainable development and sustainable urban governance, there are indications that scaling of activities from small, local projects to frameworks development and regional planning may be a way to achieve transformative sustainable impacts. This is a next step for our research along with completing the review of the existing literature search and expanding the search through Google Scholar. Validating inferences through separate assessment by different researchers and combining this review with that of the literature on the use of technology in participatory planning are also important steps to achieve a comprehensive review and address its current limitations.

Living Apartment Buildings in Ankara and Their Relation with the City

Bahar Gedikli

Middle East Technical University, gedikli@metu.edu.tr

Abstract: Innovative buildings, with their design aspects, functions and environmental relations, can enrich urban areas spatially and functionally. This study explores inner-city apartment buildings in Ankara that adapted a similar approach to Le Corbusier's Unité d'Habitation (dwelling unit), and analyzes how they have contributed to their surrounding area. Le Corbusier's approach to city planning involved geometric forms. In his works on city planning, dwelling is the fundamental element. One of his well-known contributions in this regard is Unité d'Habitation. Besides its architectural features, a remarkable aspect of this model is its communal spaces. It is more than an apartment building; where he emphasized a communal lifestyle along interior streets and on the roof. The emptied ground floor and roof garden allow a social environment for users, and these spaces interconnect with nature. A similar approach was adapted by a few cooperative housing initiatives in Ankara during the 1950s-1960s period. It was a period when cooperative housing was largely implemented to respond the housing need of working population. The examples in Ankara are still well-known with their architectural styles and functional aspects. This study focuses on some of them, designed and constructed in the same period. It analyzes the morphological and functional features at street-scale. The study does not propose this approach or similar ones as a solution to all contexts, but it highlights how an architectural approach can interrelate to the urban level with its communal spaces, and open areas at ground and roof levels, and contribute to urban life in spatial and functional terms.

Keywords: apartment building, morphology, street-scale analysis

Introduction

Physical volumes, open areas and ensemble of relationship between them are the main elements of urban morphology. Such volumes, or architectural elements, can sometimes act as significant landmarks, images or nodes in cities: Some regular functional buildings, such as residential buildings, may become a landmark or part of the urban image, as they have strong visual or functional relations with the surrounding urban setting with their design qualities. Their layout, orientation, position on the plot, and architectural features can enrich the urban setting.

This study focuses on some apartment buildings built in Ankara in the 1950s and 1960s, which followed a similar approach to Le Corbusier's "Unité d'Habitation" (dwelling unit), with the aim of displaying their roles in the city and representing their design connections with the surrounding physical setting through a street-scale analysis.

The cases undertaken in this study, as Unité d'Habitation, are elevated from the ground on columns (pilotis) and comprise open common spaces both at ground and roof levels. They are worth analyzing, as they are interacting with the urban environment with their open and semi-open spaces, which are perceivable from outside. These spaces are walkable and livable and act as common places for residents. Moreover, the architectural style of these residential buildings gives them a distinguishing effect. The examples that resemble the Unité d'Habitation model in Ankara are

mainly cooperative housing initiatives, as this model allows users to socialize in common spaces. The study portrays the design aspects of these initiatives basically with regard to their street-scale perception, and analyzes how they have gradually contributed to their surrounding urban setting aesthetically and functionally.

Housing Morphology in Ankara

Spatial organizations of dwellings can be quite different in different periods, cultures and societies. Societies reflect their characters in their dwellings. Different dwelling layouts produce diverse morphologies in cities (Sungur and Çağdaş, 2003). In addition, façades of dwellings also identify the quality of urban environments to a great extent. The aesthetic and innovative approach to façades can raise the quality of urban environment (Basa and Şenyapılı, 2006).

With regard to different dwelling types, Gökçe and Chen (2017) identify five morphological periods in Ankara:

- *1923–1950s: The Early Republic Period*
There was a housing shortage after the 1st World War. Garden City dwelling type was seen as the ideal style for the city. Apartment buildings emerged, too.
- *1950s–1980s: Modernization Period*
With rapid migration to the city, construction of informal houses remarkably increased. Meanwhile, apartment buildings became widespread and replaced the garden houses. The apartment lifestyle was widely adopted by the community.
- *1980s–2000: The Liberalization Period*
Housing production declined. Besides, there was a significant decline in the ratio of slums. Housing cooperatives were established. Gated communities were launched.
- *2000 to date: The Contemporary Period*
Urban regeneration was introduced and became widespread. Gated communities have increased. Mixed-use housing developments are also widely constructed at present.

Before the 1950s, the common housing type in Ankara was single detached housing (Figure 1, Çalışkan, 2015). Two successive plans, namely the 1924 Plan by Karl Lörcher and the 1927 Plan by Herman Jansen, determined the development of the city in this period. The Jansen Plan, which was attained through an international planning competition, proposed low-storey, detached housing areas and low-density development for the city. Consequently, single or low-storey detached housing identified the urban image and morphology of the pre-1950 period in the city (Çalışkan, 2015).

Figure 1- Main housing morphology in Ankara before the 1950s (Çalışkan, 2015)

The years following the 1950s saw a remarkable increase of population in Ankara. As the city had grown more than predicted in the Jansen Plan, a new international planning competition was organized in 1955 to attain the new city plan. The winning plan was designed by Raşit Uybadin and Nihat Yücel, which proposed a homogenous city packed within the municipality boundaries (Günay, 1992, 34). The plan, like the previous one, maintained the growth of the

city towards the south of the existing city, namely towards the Kavaklıdere and Çankaya districts, and opened up the western corridor for growth.

The subsequent Law on Flat Ownership (1965) allowed more than one ownership within one single plot, which led to the dominant dwelling typology in Turkish cities, mainly composed of apartment buildings (Figure 2, Çalışkan, 2015). The Law, therefore, marks a turning point in terms of housing production that defines the new image of Ankara streets. Three- to five-floor apartment buildings were allowed in different districts. Low-storey garden houses of the early Republican era were largely replaced. The most common typology after 1950 was the reinforced concrete, multi-storey apartment building, which changed the city's traditional image (Ultav, 2019).

Figure 2- Main housing morphology in Ankara throughout the 1950s and 1980s (Çalışkan, 2015)

Actually, multi-storey apartment buildings were not new to urban dwellers in the midst of the 20th century. Particularly in Istanbul, the 19th and early 20th century apartment buildings in various styles were present. However, throughout the 1950s and 1960s, the above-mentioned Law led to widespread production of apartment buildings mainly by housing cooperatives, individual developers, and mass housing companies, parallel to the rapid population increase. This led to the repetitive production of this building type (Gürel, 2009).

The cases elaborated in this study were produced by housing cooperatives, when the apartment-type dwellings started to expand in Ankara. A study by Ürey (2012) indicates that between the years 1948 and 1962, housing production was mostly led by cooperatives in Ankara, which occupied 60% of total housing production. The total number of cooperatives were 391 in this period, 184 of which were in Ankara (Cengizkan, 2000, cited in Ürey, 2012). Meanwhile, the number of building permits given for apartment buildings raised gradually from the 1950s onwards, while those for single houses diminished (Table 1).

Year	Single Houses	Apartment Buildings
1954	1500	279
1955	1049	341
1956	1037	330
1957	726	473
1958	440	846
1959	263	418
1960	89	622
1961	132	644
1962	66	799
1963	358	481
1964	85	575

Table 1-Number of Building Permits given for Single Houses and Apartment Buildings between 1954-1964 in Ankara (Akin, 2007)

Design Aspects of Apartment Buildings and Dwelling Morphology

In the 1950s and 1960s, the apartment signified modern living. Architects, following the socio-economic trends in larger cities, attempted new architectural styles in apartment buildings to support the modern lifestyles of families (Güney, 2008). Their plans were mainly for nuclear families. The new housing areas that started in the 1950s were remarkably different than the traditional parts of the city. It was a period when Turkish architects were impacted by international trends. They followed the international style, and formulated the plans of their buildings upon prismatic forms. Architects and builders embraced apartment buildings as integral to urbanization, modernization, and higher living standards. These buildings can be seen as outputs of architectural modernism, which regarded the simple look as a sign of civilization (Gürel, 2009). The design of apartment buildings depended on geometric forms, leading to a homogeneous morphology in housing areas (Aykut, 1998). Güney (2008) identifies that, like traditional Turkish houses, apartment buildings also have an outward-looking configuration.

The apartment buildings of the period, consequently, were largely characterized by multi-storey, rectangular masses. As plan layouts reflected geometric and orthogonal forms, the ensemble of these masses composed homogenous streetscapes in residential areas. These buildings, in a short time, constituted the main morphological style in the metropolitan cities (Güney, 2008). The façades of buildings produced throughout the 1950s and 1960s displayed simplicity and rationality (Tapan, 2007, cited in Suoğlu, 2009). Bozdoğan (2016) states that the façades of the period were treated as a form of modern decoration, an orthogonal grid to be filled with glaze, brick or plastered geometric elements.

Figure 3- Façade decoration example

Figure 4- Façade decoration example

The apartment buildings produced throughout the 1950-1980 period, i.e. the second morphological period as identified by Gökçe and Chen (2017), compose a repetitive streetscape in residential areas. The modernist approach to building design and identical setback distances in plot arrangements led to a homogenous solid-void relationship on residential streets.

Different Design Attempts for Common Living

The cases elaborated in this study are located in the Kavaklıdere and Çankaya districts, all of which were produced by housing cooperatives. They are Hayat Apartment Building (1957), Cinnah 19 Apartment Building (1957) and İş Bank Apartment Buildings (1962). The residential buildings produced via housing cooperatives assumed different typologies, either in the form of several apartment buildings on a block or one single apartment building on a plot. The examples in this study refer to both types. The cases investigated are almost aligned on a linear axis starting from Kavaklıdere, following a major inner-city boulevard to the south and ends up at Çankaya (Figure 5). The Uybadin-Yücel Plan, as mentioned before, supported the development of the city towards the south, i.e. towards the mentioned districts, and the morphology of these districts developed with this plan.

Figure 5- Location of the cases (Google Earth image)

Residential areas and buildings are significant components of the urban image. Different housing typologies compose different streetscapes and urban patterns. The relation of a residential building with the surrounding urban area can be described with regard to its own design features (its form, its façade, its entrance, its open/semi-open components), its position and orientation on the plot (the relation with the plot), and its relation with the masses and open spaces that surround it.

The design approaches followed in all three examples are similar to Le Corbusier's approach to dwellings. As known, Le Corbusier's approach to city planning involved geometric forms, regularity and standardization. In his works on city planning, dwelling is always the fundamental element. His well-known research and practical contribution in this regard is Unité d'Habitation. Besides its architectural features, a remarkable aspect of this model is its communal spaces. It is more than an apartment building; rather, a "vertical garden city", where he emphasized a communal lifestyle with public uses along interior streets and on the roof. The building is designed like a vertical neighborhood, with a rich community life, while still having privacy in apartments (<https://www.archdaily.com/85971/ad-classics-unite-d-habitation-le-corbusier>).

This study notes to the model's ability to provide a social environment for its users and interconnect with the surrounding urban setting: The open plan and free façade aspects of the model, the open ground level, and the roof

garden can be seen as components of Unité d'Habitation that provide these interactions. The freed ground and roof garden are places for both communal uses and connection to nature. Obviously, there are many other design approaches to dwellings that emphasize communal life, and provide connections to the surrounding urban space. The study focuses on this model and illustrates it in the Ankara case, as they are well-known architectural examples in the city.

A Street-Scale Analysis of the Cases

Residential buildings comprise private realms, but when they are aligned along a street, they compose a streetscape for the eyes and perception of the public. A streetscape is, therefore, a transition space between the private and public realms. Public and private spaces cannot work independently, rather, they complement each other (Bentley et al, 1985, cited in Songülen 2012). The transition space that they compose together is an interface between internal and external areas. As the public have the right to look at buildings and share some symbolic possession, the owner of a dwelling has some right to view the external realm and exert their influence on the common space. Consequently, the relation between the public and private spaces in a streetscape is an important determinant of its character (Tucker et al., 2005).

To evaluate how the chosen apartment buildings contribute to the townscape and urban image, a street-scale analysis is conducted with regard to the dominant features of the residential streetscape. Plot is one of the fundamental elements of urban form, the pattern of which depends on property boundaries. The individual plot, together with its building or buildings and open spaces, is the smallest unit in a city. The characteristics of this unit define the urban form, its shape and density, as well as its actual and potential function over time (Moudon, 1997). A row of plots, placed next to each other along the same street-line forms a plot series (Conzen, 1960). This series is the matter of street-scale analysis. The street-scale analysis in this study first focuses on the plot arrangement, arrangement of buildings in the plots and access patterns from the street to the private entrances as adapted from Gökçe and Chen (2017). Additionally, housing type, number of stories, building codes and façade view are also analyzed.

Hayat Apartment Block

Hayat Apartment Building was designed by Emin Halid Onat, one of the pioneers of modern architecture in Turkey. He designed it through an inclusive approach, where the cultural, artistic and social needs of a family could be met within one building, i.e. similar to the Unité d'Habitation model. It was constructed on a 5000 sqm-land by the Hayat Building Cooperative in 1957 (Şumnu, 2017).

The building is taller compared to the other residential buildings in the block it located on. Originally, the building was designed with a roof garden that would contain a cinema and a club. However, this level could not be built due to inadequate budget. The ground level is freed and the building is elevated on pilotis (Figure 6). It consisted of four shops, a patisserie, a hairdresser's shop, an office and a nightclub (Şumnu, 2017). The nightclub was active throughout the 1960s and 1970s, which attracted many citizens of Ankara (Resuloğlu, 2014).

Figure 6- The Hayat Building lifted from the ground on pilotis
(Source: Social media page for the building)

Hayat Apartment Building is still a residential building. Its central location at the junction of a major commercial street and an urban park gives it a distinctive effect in the city. In its vicinity there are some landmarks of the city, together with which it contributes to the urban silhouette (Figure 7).

Figure 7- Hayat Apartment Building in the urban view with other landmarks

Street-Scale Analysis

The Hayat Apartment Building is located along a major boulevard of the city, which accommodates commercial and business uses. The plots on the building block are not at same sizes as they host buildings for different functions. Nevertheless, buildings are located on these plots with respect to identified minimum setback distances. Hayat Building, meanwhile, is located in the midst of its plot. Five plots were merged and the building is settled towards the middle of the merged area, allowing a large public open space at the front and back (Figure 8-9). The access to the private realm is not directly from the street, but after this open public space.

Figure 8- The urban morphology of the area, with Hayat Apartment Building using the plot different than other residential buildings (Google Earth image)

Figure 9- Rear façade and garden

The residential buildings in the area are constructed as detached buildings. The Hayat Building is a prismatic apartment building with 7 stories and ground level. In accordance with the modernist approach, its façades reflect simplicity. The only decoration is at the back façade, i.e. gridded openings obeying the simplicity approach of modern architecture.

Figure 10-Façade decoration

Because of the budgetary limits, the roof level could not be built, which would provide a scenic relationship with the urban setting. Still, the ground level shops and open areas in front of them are interrelated to the public realm. Besides, the position of the building on the plot, its large façade and height contribute to the urban image in a strong way, which makes it one of the landmarks of the area.

Cinnah 19 Apartment Building

The Cinnah 19 Building, which was named after the Cinnah Boulevard, was constructed for the Workers' Cooperative of Directorate of Ports in 1957. It is treated as an experimental building even today. The Cooperative was established by the engineers and architects of the Directorate, and constructed through the loans provided by the Workers Insurance Institute. The architect paid attention to daily social practices, therefore aimed at creating gathering places in the building (<https://www.arkitektuel.com/cinnah-19/>). Like the other two cases, the building is also lifted from the ground with pilotis. There is a pool, a bar, a fireplace, sunbathing places, a shower bath, locker rooms, and toilet at the roof

level, and a garden at the ground level (Figures 11-12). The places at the roof level were conceived for interaction among neighbors and with the surrounding urban environment. This level is no longer in use.

Figure 11- Pool and fireplace at roof level

Figure 12- Garden at ground level

The architect Nejat Ersin mentions that what he aimed was to handle the project in a different way than the cooperative buildings that had been built so far in the city. He, himself, also worked in the same Directorate as the chief of the

Office of Architecture. The future residents of the building, his colleagues, encouraged him to design an unconventional apartment building, which should be different than the existing ones produced through housing cooperatives (Interview conducted with the architect, <http://dergi.mo.org.tr/dergiler/4/553/8277.pdf>).

Street-Scale Analysis

The plot arrangement on the Cinnah Boulevard has a rectangular form with almost identical sizes and identified setback distances. The buildings facing the boulevard were designed and built as residential apartment houses in prismatic forms. Ground floors of the buildings are for commercial purposes. The buildings have direct access to the sidewalk and they have private gardens behind them. They are purely aligned along the Boulevard.

The residential buildings in the area are all detached buildings. The height of Cinnah 19 is the same with the ones next to it, although there are 3 floors over the ground level, and 2 floors below it. Untypically, the façade of the Cinnah 19 was not oriented towards the main street, but to the adjacent plot. The idea was to integrate the semi-open places of the building with the urban view. The apartments have connections with the surrounding urban setting, since their doors open to these semi-open balcony-like corridors. (Figure 14-18).

Ersin explains that he was inspired by Le Corbusier, Oscar Niemeyer, Lucio Costa, Edward Durrell Stone, among which Corbusier's housing blocks particularly interested him with regard to duplex apartments in a residential building. He aimed at creating equal living conditions for the residents. He was motivated by the housing complex in Marseille, as the building provides the dweller cozy flats and a comfortable way of life. In the façade design, he was inspired by Stone, who used white concrete grills in his buildings. In a modernist simplistic way, Ersin applied this idea as rectangles on the façade (Interview with the architect in URL: <http://dergi.mo.org.tr/dergiler/4/553/8277.pdf>).

Figure 19- Façade design of the building

Figure 20- Relation with the street, entrance of the building

İş Bank Buildings

The İş Bank Apartment Buildings were led by the İş Bank Civil Servants Building Cooperative. They are composed of 10 blocks, which were designed in three different types in 9 stories, ground and roof levels. They were located in three building blocks next to to each other (Figure 21). The architect Kadri Erkman paid close attention to the solid&void relationship on the block, and the vacant area between the buildings was conceived as a common place to be used by dwellers (Şumnu, 2017).

Figure 21- İş Bank Apartment Buildings

(Source: <http://sivilmimaribellekankara.com/YapiDetayi.aspx?anah=264>)

Street-Scale Analysis

The plot arrangement of the neighborhood has a rectangular form linearly arranged along the streets. The rectangular plots have almost identical sizes to host buildings of similar sizes. The buildings are all apartment houses in prismatic

forms, located on the plots with respect to setback distances and leaving semi-public open spaces in front of and behind them. They are all detached buildings purely aligned along streets.

The plots of the İş Bank Apartment Buildings, however, were merged to attain a communal space for the entire buildings of the cooperative initiative. The 10 apartment buildings are gathered in 3 building blocks next to each other. The buildings are located in accordance with the setback distances in the neighborhood, however, the way buildings come together is quite different than the others in the neighborhood which creates a dynamic solid&void relationship. They are positioned in a way to create common open places in each building block (Figures 22-24).

Figure 22- Plot and building arrangement (Google Earth image)

Figure 23- Open places for common use

Figure 24- Building entrance, relation with the street

Besides the green spaces between residential blocks, there are common places also for the dwellers in the individual blocks. Apart from being prismatic masses, the design of buildings is rather different than the others in the neighborhood following a Corbusian style. They are lifted from the ground as in the case of Unité d'Habitation, and ground levels are designed as open, semi-closed and closed common places (Figures 25-27). At the ground level, there is a closed area comprising a fireplace around which the dwellers could come together. The walls of the area are glass providing visual interaction with outdoors (Şumnu, 2017). At present, the ground levels of six of the blocks have been transformed to commercial spaces like patisserie, kindergarten and so on (Sudaş, 2010).

Figure 25-The buildings are lifted from the ground with pilotis.

Figure 26-Open space for common use at ground floor, creating visual continuity.

Figure 27- Open and closed social places at ground level, blending with the surrounding landscape.

Likewise, there are open, semi-closed and closed spaces at the roof level as common places. The roof gardens have been used for party organizations and sun-bathing purposes (Sudaş, 2010). The design of the roof garden comprises intensive use of greenery.

Conclusion

Different dwelling layouts produce diverse morphologies in cities. This study has portrayed the development of apartment building typology in Ankara particularly after the 1950s, which were mainly characterized as multi-storey rectangular masses. These buildings, in a short time, constituted the main morphology of residential areas. The study has then discussed how different design approaches to housing within a streetscape can contribute to the urban image, and exemplified it in models similar to Unité d'Habitation. The study does not propose Unité d'Habitation or similar models as a solution for all contexts, however, as it inspired later generations in urban design and architecture, it portrayed the approach that the model has offered for communal life.

Plot is one of the basic elements in the overall morphology of cities, which are given definite urban codes in development plans, i.e. type of land-use, building codes, etc. This paper has illustrated how a design research on a residential plot can interconnect the internal and external spheres of a residential building, and contribute to the social life of its dwellers. The three cases are known as significant architectural elements in the city: Cinnah 19 is still a residential building, but it has also become a significant niche for artistic uses. There are art galleries, architecture and design offices in the building. Meanwhile, Hayat Building has become a landmark in the urban scene although it is a residential building. Ground level is used by private shops with the semi-public open spaces. İş Bank Buildings are in a residential area, and the way the plots are used provide larger green spaces for its users compared to the other dwellings in the area. Moreover the terrace level has strong visual connections to the urban scene, it allows the users to enjoy the external urban environment.

All these cases have interactions with the urban environment with their open and semi-open spaces, which are perceivable from outside. Besides, the design approach followed in these buildings gives them a characteristic effect, which distinguishes them then the others in the townscape. These cases have shown a design research for enhancing communal life within the residential building itself, and integrating with the urban and natural environment. They illustrate how design relations within the plot, transition from building to street level, and interactions with the surrounding area can enrich the urban setting.

Research on renewal of leftover spaces based on multi-actor planning

Yuchen Guo¹, Burcin Baykurt², Shuyuan Dai³

³Tongji University, China, yvonnedsy@tongji.edu.cn

Abstract: Leftover spaces in cities are becoming a global issue. Having undergone significant changes in historical, spatial, political and socio-economical aspects, the number of leftover spaces has been increasing year by year. Now cities are facing the challenge of integrating them into their urban fabric. This research first focuses on worldwide cases that show the current approaches to re-use these leftover spaces, and then systematically classifies them according to their multi-actor planning strategies. The classification includes: diverse models (top-down, bottom-up, public-private partnership) by engaging with different actors at various levels of participation. China has its own urban renewal rules and policy system. Influenced by factors such as its state structure and economic system, China and the West have many differences. Based on the case classification that provide a worldwide overview and the real condition in China together with its existing needs, this study develops “City 360” platform as a democratic, multi-level planning tool and an innovative method to tackle the following problems in leftover space renewal process: simplification resulting in social inequality, information imbalance, resources/funds shortage and diversification encouraging urban complexity, inclusive planning. “City 360” turns the process of leftover space renewal from an urban simplification into an urban diversification, and responds to high-level challenges. Having integrated multiple actors into a participative process creates collaborative urban governance, which can balance the power among state, society and market, and maximize the cooperation in between government, private sector, community self-governing organizations, volunteer organizations and residents. This innovative, inclusive multi-level planning tool helps integrating development resources, promotes the vitality in developing urban communities. It aims creating a new level in Chinese urbanization, which has started with “traditional governance” and transformed into “multi-level governance”. The goal is now “traditional governance” to “governance” to “good governance”.

Keywords: Leftover Space, Multi-level Governance, Multi-actor Participation, City 360

1. Introduction

In late 1980s, when Thomas Trancik has first referred leftover spaces in his book “Finding Lost Space”, he was describing them as spaces “*that are in need of re-design, making no positive contribution to the surrounds or users*” (Trancik, 1986, p.3). Over years the issue of leftover space has not only generated series of definitions in worldwide (“*cracks in the cities*” (Loukaitou-Sideris, 1996), “*vacant lands*” (Pagano & Bowman, 2000), “*in between spaces*” (Hajer & Reijndorp, 2001), “*spaces of uncertainty*” (Muller and Busmann, 2002), “*slack spaces*” (Worpole & Knox, 2007),

“zombie properties” (Silverman, Yin and Patterson, 2013), but also comes in different aspects in contemporary cities. Their contribution to their surroundings and users varies in different cases, as contrary to what Trancik limitedly described three decades ago.

Spatially speaking the scale of a leftover space range between the building, plot, block or even to the neighborhood scale (Azhar & Gjerde, 2016). This can be so interpreted that, these spaces can take place in between, underneath, around or top of the buildings. They can be publicly or privately owned, but they can be also no man’s land that left abandoned for years. The examination of the leftover spaces has shown that they vary not only in forms, locations or their property types, but also in aspects that trigger them to happen. But why has the number of leftover spaces been increasing in recent years?

To answer this question is anything, but simple. It is only clear that leftover spaces are products of significant changes that cities have undergone in historical, spatial, political and socio-economical aspects. That’s why in a German city a leftover space can be a potential tool for opening new discussions to address urban shrinking (Dubeaux, Cunningham, Emmanuèle, 2017), but on the other hand the same spaces can turn an economic fallacy for a neighborhood in USA into an effective financial strategy to flourish again (Forbes, 2012). In UK, for example, leftover spaces can be developed to evoke the property owners that stuck into current real estate policies (The Guardian, 2018). Or in Kuala Lumpur they can trigger series of public space activities by transforming the “unsafe” into “livable” as Jane Jacobs emphasized the importance of the need “eyes upon the street” decades ago (Zaman et.al, 2012). All these cases from various parts of the world show that leftover spaces can be conceptualized in different locations with diverse motives and aims. Although they may have different political and socio-economical systems, the global perspective of this issue has a great potential to offer possible interactions between cases when it comes to realization.

China, on the other hand, separates itself from other countries regarding the ways of dealing with leftover spaces. China has its own urban renewal rules together with its own urban policies. Given to its state structure and economic system, it is clear that China and the West have many differences. However, recent economic reforms and drastic shifts in the structure of Chinese government allow us to think about the possibilities to envision new levels of participation and communication in urban planning.

This paper aims to investigate new planning strategies, which can be developed by engaging with different actors and levels of participation in order to integrate leftover spaces into urban settings of Chinese cities. First, it focuses on worldwide cases that show the current approaches to re-use these leftover spaces, and then classifies them as models according to their multi-actor planning strategies. These diverse models include top-down, bottom-up, public-private partnerships and collaborations, which bring together government, private sector, non-profit organizations, academia, artists and locals. By linking this assessment of case studies with Chinese urban situation, the paper focuses on the current climate in China in terms of dealing with increasing number of leftover spaces. Following that this paper introduces the project “City 360”, which aims creating a new level in Chinese urbanization by integrating multi-level planning tools in the light of analytical interpretation of worldwide cases.

2.1. Literature review

Having critically analyzed the current approaches in the literature, it is seen that the main focus has been mostly on the ways of reusing leftover spaces by emphasizing its design elements. But in the absence of constructive planning tools together with the participation of multiple stakeholders, only design itself may not be sustainable. In order to reveal the critical role of participation and communication at various levels, this literature review focuses on a historical overview of transforming / governing leftover spaces in cities.

In 1998 Barry Wood looked at four European countries in terms of approaching leftover spaces and their development. Although the study was conducted nearly three decades ago, he concluded his study something very global by noting, “the causes of vacant land are clearly seen to be changing, and most importantly not declining” (Wood, 1998). Based on his study, the emergence of leftover spaces could be driven by suburbanization, deindustrialization, migration, inefficient allocation of goods and services in city (Wood 1998; Bowman and Pagano 2000). In the context of Europe, by the 1980s the populations of European cities, where the industry had dominated for years began to decline. According to Haase et. al, approximately 40% of European cities were losing population and experiencing de-densification, which let the emergence of leftover spaces (2014). During mid-80s in Germany there were about 25 million square meters, 22 million were in Britain, 10 millions in the Netherlands and in Italy about 6.4 million brownfields were listed as vacant (Errigo, 2013).

Given the fact that the traditional planning tools in Europe has been zoning and master planning, which meant big financial capital and non-flexible process of implementation, managing leftover spaces in modern world needed innovative strategies (SUC, 16). Instead of having a concrete plan, it is seen that transformation of a leftover space could adapt itself over the process, with the participation of users and other stakeholders. Transforming the abandoned Cable & Wire Factory district (KDAG) in Vienna, for example, has started in 1998 with the aim of creating a new and improved image for the district and finalized in 2007 by becoming one of the good examples for changing the understanding of managing vacant spaces (Pamer, 2007).

Meanwhile in Germany dealing with these leftover areas in cities has taken place much later than acknowledging them. In 1994, Firebrace in his book “Jasmine Way” mentions, “*The existence of these vacant spaces has never been officially acknowledged. On the city map they were covered over with fictitious streets, reflecting of the shame that Berlin is not like other cities with their respectable centers*” (Firebrace, W., 63-66). In 2006, 14,4% of Berlin's urbanized areas was classified as “vacant spaces” (Colomb, 2012). Given the fact that Berlin among other German cities found itself in a big financial burden after World Wars, these vacant areas needed to be not only acknowledged but also developed. 2001-2003, a group of architects and urban planners, known as Urban Catalyst, has started to investigate the potential of transforming these vacant spaces as temporarily. Berlin was one of their case studies and in 2007 together with city officials in Berlin they have initiated a conceptual plan by emphasizing high social and economic value of leftover spaces for the city (SenStadt, 2007). In other words, they emphasized the image of Berlin as a “creative city” by revitalizing these leftover spaces for short-term uses.

Years later, as one of the biggest urban projects in Germany, Hafencity, came to the attention. The country had been suffering from deindustrialization since mid 1980s and that's why this huge port

area needed to be developed in a way that the needs of residents should be fulfilled. Hafencity began as a master plan, which was very familiar to European traditional zoning and planning tools. However, in 2010 a revision on eastern district of the project took place, where it has been originally determined for a concrete development. The city officials have decided to leave the space open to temporary and innovative uses in the light of local needs (Urban Catalyst, 2013). Once again, the renewing the leftover spaces for temporary use by taking the local needs seriously became an urban strategy for a city.

Starting from 1960s in United Kingdom the issue of leftover spaces has developed differently than other European cities. Under severe housing crises, the “Squatting Movement” which refers claiming possession without being owner of area started in London first and then spread to other boroughs (Bosetti, 2018). Given the fact that 30,000 people lived in squatted accommodation in UK for years, it would be not wrong to say that the aim of using leftover spaces became a part of urban history (Bosetti, 2018). A current report shows that across the city the vacant lands, which were left abandoned for six months and more reaches up to 2,700 hectares (Sullivan, 2018). Having underestimated the risks of leaving the areas empty and lacked of effective planning tools to improve the quality of space becomes the main reasons to end up the raising numbers for leftover spaces across the country (Bosetti, 2018). Although UK has also acknowledged the fact that renewing leftover spaces brings many improvements into city life and city economy, still there are some challenges to tackle. According to this report from 2018, it is seen that city officials has to step in by engaging the role of “mediator” and begin more effective to convince the landowners about the potential of re-using these spaces as “meanwhile spaces” (Bosetti, 2018).

While Europe has been dealing with its vacant spaces by implementing more “dynamic” and “effective” urban planning tools, USA on the other hand, needed to deal first with the diversity of its leftover spaces, which came into different types and characters in all over the country (Pagano and Bowman 2000). Cities such as Detroit, Michigan and Baltimore, Maryland have been going through similar post-industrial phase, as many European Cities in mid 80s. However, the issue of leftover spaces was also very vivid when it comes to growing cities such as Phoenix Arizona, which has had 43% land vacancy after its population increased by 55% (Pagano and Bowman 2000). The biggest challenge for USA has been the necessity to deal with each city with its own rates of population and land area growth by analyzing its abandoned structures and asking customized questions (Pagano and Bowman 2000).

According to a current inventory of vacant land and structural abandonment in United States conducted in 2016, the most commonly referred reason for increases in vacant areas is the lack of reinvestment of capital. Suburbanization and deindustrialization were following as the leading causes of vacancy since 2000 study by Pagano and Bowman (Newman, Bowman, Kim, 2016). The 2016 Study also shows that the main reasons of decreasing leftover spaces are linked to growing local economy and city policies to reuse them (Newman, Bowman, Kim, 2016). Acknowledging leftover spaces as a potential to create a growth in local economy has been gaining ground in some American cities, such as Chicago. It is seen that traditional ways of generating this growth by providing tax incentives for new business, are no longer financially viable, instead “locally inspired” public spaces, which generated for the quality of life shows that it has a real effect on local economies (Forbes, 2012). Place making Chicago, for example, have been implementing temporary projects to turn

leftover spaces of various neighborhoods into community gardens or art exhibitions together with Metropolitan Planning Council and local residents (Placemaking Chicago, 2018).

Another good example is an organization named as 596 Acres in New York City. The organization defines itself as a community land access advocates, who believe that residents should have a say over how or who use the lands in their neighborhood (596acres). One of their projects was about turning a vacant lot into a community garden, where local residents can socialize in a community space (Kennedy, 2014). The initiative itself sounds not so unfamiliar for New Yorkers, given the fact that in the United States during economic fallacy and two World Wars, gardening in vacant lots was one of the efficient ways to create less depressive environments especially for unemployed people (Drake and Lawson 2014). However in this case the most valuable contribution of this initiative is to provide a “mediation” service for locals, who has difficulties to reach the right information and right people in city government agencies (Kennedy, 2014). In other words, this initiative fills the gap between urban policies and the local residents in a way that both government and other non-profit organizations have certain challenges to manage.

The issue of vacancy in Japan differs from Europe and USA. Except the metropolises such as Tokyo, Osaka and Nagoya, Japanese cities have been facing population loss for the last decades (Sakamoto et. al, 2017). The migration from small regional cities to large cities with the aim of having better opportunities and rapid economic growth were two main reasons for an increase in vacant land in the country (Sakamoto et. al, 2017). At political level the role of local governments in Japan has becoming very prominent, when the central government implemented the decentralization process at local level and lately most of Japanese local governments took legal actions to push the owners of vacant properties for an appropriate management (Takamura, 2015). It starts with creating a council authorized by central government in order to identify the vacant areas and its owners. Then the process continues to obligate the property owners to take an action to refurbish these areas. In the cases of not finding the real owners or not seeing any action from owner’s side, the local government has right to demolish or refurbish by its own terms (Stroud, 2015). Although the local governments receives more power over urban development, civil society was still weak and fragmented in a way that it had little influence on urban issues that concerns locals (Sorensen, Koizumi, 2009). In response to top-down central planning, which put more priority on economic growth rather than quality of life, the role of community building or in other words “town building” became more dominant on developing urban neighborhoods in Japan. Regarding vacant, leftover spaces in urban settings, community groups together with local residents and non-profit organizations have started to take actions in order to reuse these areas for the benefit of neighborhoods (Sorensen, Koizumi, 2009).

As similar with some Japanese cities, many African cities have been also rapidly urbanizing, yet the pace of their planning is still behind the city growth (Haas, 2018). As cities grow, such as Kampala, they don’t show the type of density that a productive city requires, but low-rise buildings and great urban sprawl (Haas, 2018). As a result of that, many African cities have been tackling the issue of leftover spaces, which remain for years unbuilt and undeveloped. The reasons of this emergence can vary. In some cases unclear ownership can be the main reason, why the land is being left as undeveloped. The urban land can remain also vacant to produce speculation for its price or the reason can be simply the lack of financial resources to properly develop them (Haas, 2018). Lately in Kampala it has been considered to tax these vacant lands in city at a higher rate in order to encourage the property owners for a further development (Haas & Kopanyi, 2018). This means, if there is still no

development after a certain time period, the city can legally reclaim the land. Although there are some good examples in the world, such as Bogota, where this kind of taxation works in favor of efficient use of land, the reasons why these leftover spaces have emerged in the first place and the motivations of developing these spaces for users need to be deeply analyzed (Haas, 2018).

China, on the other hand, has been dealing with its own urban transitions under the influence of its politics and economy. In China urban land belongs to the government, as a means of production by Chinese socialist state planning. Urban economy, on the other hand, has been controlled by state-owned initiatives, which were strictly controlled by the state (Zhu, 2004). This central planning, which has dominated the country for almost 30 years, has transformed into more compact and market-oriented planning as a result of the economic reforms and institutional change in 1980s (Lin, 2009). The decentralization in economy has led also a political decentralization, which means more financial power to municipal local governments (Chen, Gao, Chen, 2016). In the meantime, Chinese urban growth has begun to accelerate dramatically as a result of new economic reforms and the “open-door policy” in 1978, which aims to utilize foreign investment and engage in international trade (Chen, Gao, Chen, 2016). All of these developments and the rural to urban migration in the country have a big impact on shaping the Chinese urbanization process. Urban expansion or in other words “urban sprawl” correlates with economic growth very strongly in China. It means that local municipal governments are having strong motives to promote the economic growth by using land leasing as a tool to generate revenue (Fang, 2016). This desire of local governments to increase the amount of buildable land by converting the land from farmland without any compensation can be seen as a main driving force of urban sprawl in China (Fang, 2016). As a result of this process, it is not a surprise to see that China has been also dealing with vacant, leftover spaces, which remained as undeveloped for years. And developing these spaces based on needs of local residents comes not as a first priority under the current political influence. The politically centralized planning system in China is in a way very fragmented, complex and overlapping among different agencies at different levels of government (Evans, 2004). In other words developing an area means a competition between these different agencies and that means the whole process lacks users’ input. To be able to reuse these leftover spaces for the benefit of users requires a change in current Chinese planning tools.

2.2. Models of action for renewing leftover spaces

The literature review leads us following models regarding the renewal of leftover spaces. In the light of global overview on this topic, each of these managing/planning models is developed based on different intentions and execution patterns regarding its various needs and organizational structure. Considering this global categorization together with Chinese context, understanding these models sheds light on new possibilities in Chinese urban planning tools and new lessons to learn in governing leftover spaces in China.

Community driven model:

Community driven model for renewing leftover spaces in cities can be initiated, when a community or individuals in a neighborhood identify an unused, leftover space as an unproductive, unutilized, or in some cases criminal to the neighborhood (Kremer & Hamstead, 2015). Transforming such spaces needs some additional tools or third parties to make the process of evaluating the land potential easier. Non-profit organizations, for example, play a crucial role to provide contextual information to

individuals or communities by using online mapping platforms or organizing local gatherings (Kremeretal, 2015) (Figure 1). The initiatives from USA, including 596 Acres or Better Block, can be seen as good examples to encourage locals to integrate more into developing process of vacant lands in their neighborhood by providing needed materials or guidance. In these examples, it can be also seen that the focus is mostly on short-term developments, which refers temporary use or in other words “tactical urbanism”, which means “*low-cost, minimum effort, temporary interventions that improve the livability and aesthetics of local neighborhoods*” (Lydon, & Garcia, 2015). Taking the example of Japan, the power of “community” can be the main driven force for developing vacant spaces in city by considering the real wishes and problems of local residents. The cooperation between the communities and the government does not only improve public efficiency, but also reduces the burden on the government by solving tasks. In this process, residents have gradually deepened the relationship between each other because of their high level of participation and self-determination, and can cultivate a team belonging to the community itself, and play a virtuous circle (Kikusawa & Kondo, 2017). Without formulating any “end result”, which has been very uncommon in any traditional city planning tools, creating livable spaces with the participation of community has become one of the important models for reusing leftover spaces in cities.

What can be reflected on China in terms of managing leftover spaces in urban settings is to acknowledge the changes in understanding of urban management. As Urban Catalyst, a group of architects and designers from Berlin emphasizes, now “*the focus is not on urban design, but urban use* (Urban Catalyst). What that means in our contemporary cities is to let the decision of how to use vacant areas to local communities, in other words actual users. And very different from top-down planning tools, the main aim is not push people to follow certain master plans, which were mostly prepared in favor of economic growth rather than quality of life, but to create an interactive platform, where all the stakeholders can meet, discuss and decide together.

Figure 1. Community driven model

Source: Author

Government driven model:

Government driven models have become very common strategy in managing leftover spaces, especially in Europe. Based on the current examples of this model, it is seen that the scale of the projects extends and time of usage is mostly considered as long term.

The planning process happens, where government takes the role of “mediator”, rather than “decider”. Given the fact that the traditional planning tools as master plans have been applied in Europe for years, dealing with leftover spaces with an innovative strategy can be considered as a big step. This paradigm change in development of leftover spaces can be seen in many other current projects in Europe, which have been initiated first by government and been delegated to various agencies, non-profit organizations and related foundations. And for these projects the government was playing not the role of decision maker but the role of “mediator” in between various organizations, agencies and local residents. This role of mediator can be also interpreted as an “enabler”, where the government starts enabling the communication between different parties and stakeholders (Figure 2). And in some cases the government enables the impact of property owners by helping them financially in order to manage their vacant lots (Urban Catalyst). Hafencity in Hamburg, where the government decided to leave the space open to temporary and innovative uses in the light of local needs (Urban Catalyst, 2013) or Urban Living Lab initiative in Amsterdam, which creates a platform to connect multiple stakeholders from multiple organizations and expertise, while the users play an active role as co-innovators in the process can be good examples to understand this new role of government (Westerlund & Leminen, 2011). This planning model basically ensures not to let government dominate the planning decisions by providing top-down projects, which is mostly not prioritizing the needs of local residents and let residents or in other words “users” to play an active role.

The most important input from these examples for Chinese context can be the balance in “intervention” of governments. Although government agencies/city officials seem to be initiators for those long-term big scale projects, it is clear that the aim is not to dominate the process in a way that they might compromise the “multi-actorness”. The cooperation between residents and various organizations together with urban experts/professionals becomes a vital element in order to sustain planning process.

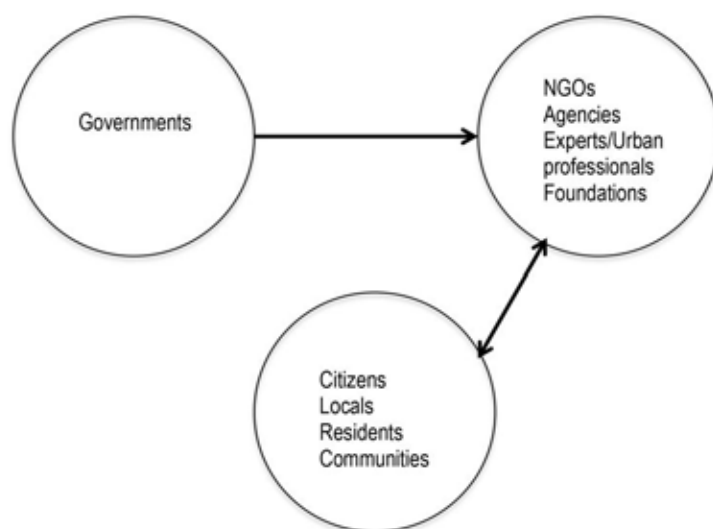

Figure 2. Government driven model

Source: Author

Artist/Designer/Architect-driven model:

In this model of renewing leftover spaces in cities, the main initiator happens a local artist, designer or an architect as a local resident or urban activist, who concerns about his/her neighborhood (Figure 3). It can be a temporary action to reuse the vacant lots in city, as in Berlin, where this “temporariness” becomes an urban strategy to promote the city. For example, Spacebuster, an art project from Raumlabor, aims to explore the qualities and possibilities of vacant lands in city (Raumlabor). It is a mobile inflatable structure – a portable, expandable pavilion, which creates a space for almost 80 people and organically adjusts itself to its surroundings (Raumlabor). This womb-like space created by artists becomes capable of transforming any one of the cities’ inhospitable, abandoned, leftover spaces into a gathering place. On the other hand, this model can refer a long-term action, which aims not only to reuse leftover spaces in favor of locals, but also to change the character of a neighborhood. In the case of Cohen Alley, in other words Tenderloin National Forest in USA, an artist, who was later supported by locals, citywide and national organizations aimed to turn crime filling leftover public space into world’s smallest “forest”. The process took almost 9 years to complete but with this initiative, over the last three decades, this dead-end alley that once stored dumpsters has been transformed into a thriving arts space (Hulkower, 2012).

What it can be reflected on China is to acknowledge the impact of designers, artists and experts, who has knowledge to provide contextual information and guidance to develop leftover spaces by collaborating with local residents and communities.

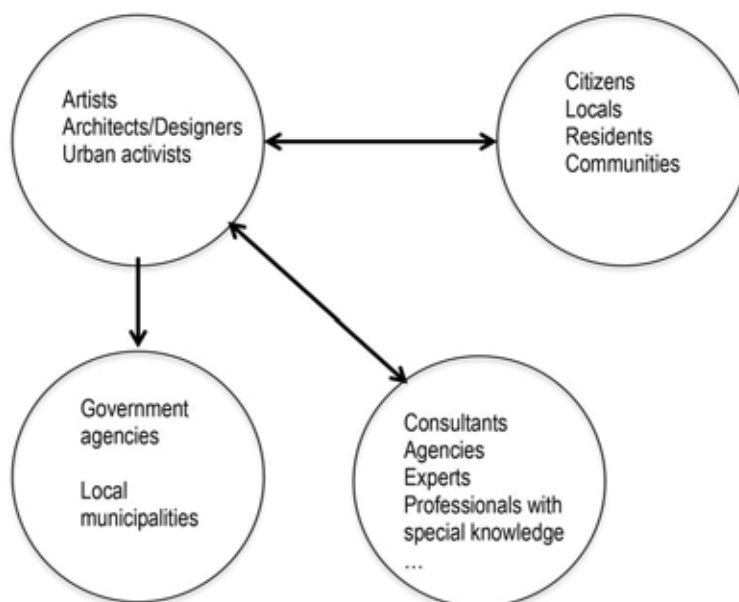

Figure 3. Artist/Designer/Architect driven model

Source: Author

3. China mode

In the light of above case analysis and classification, this part presents first the problems that China faces, and latter a suitable model that the country can adopt in terms of dealing with leftover spaces.

3.1. Problems in the process of China's leftover space

(1) Power conflicts between the state, society, and the market

China has promoted community governance for more than 30 years (Fulong Wu, 2003). Resident autonomous organizations and voluntary community organizations are maturing, and enterprises are also improving the level of public services. The enthusiasm of community residents to participate in community governance is improving. However, in the current process of leftover space renewal, the power allocation of the powers of the state, society and market is not standardized

(2) "No distinction between political and social organizations"

As mentioned in case study, there are many subjects that can participate in the process of over space transformation, which is seen worldwide. However, in China, street offices and neighborhood committees are two different entities that represent the country and society. The street office can be understood as a grassroots government and belongs to the state dispatching agency. The neighborhood committee is an institution formed by the people's self-government or democratic management. In Chinese cities, the community exists in the form of a neighborhood committee, which is an autonomous organization of residents and accepts the leadership of the street office.

However, the government has led most of community renewal. The street offices overcharge a large number of work in the neighborhood committee. It also indirectly leads to fewer participants (Liu Zekun etc,2018).

(3) Lack of entire process renewal

China's current leftover space renewal model has a long process and a long period of time. The participants in each stages are different and the information transmission efficiency is low. After the completion of renewal, there is a lack of follow-up supporting service tracking. And the continuity after renewal is poor.

3.2. Problems of actors in China's leftover space renewal

3.2.1. Supply side cannot function

Government departments, private departments, designers, community self-governing organizations, volunteer organizations, university students, etc.

(1) National power represented by the government and the neighborhood office

For the grassroots city managers, updating the leftover space actually faces a relatively contradictory situation. On the one hand, the higher-level government has issued tasks, and the grassroots managers are willing to solve the problem; on the other hand, they lack professional knowledge and lack

communication channels with professional designers. At the same time, due to issues such as the annual budget approval process, they also face the problem of limited budget and cost control (Li Xiao, 2018).

(2) Social forces represented by community self-governing organizations, volunteer organizations, and university student service teams

At present, the cultivation of volunteer organizations participating in community governance in China is not in place because government departments and officials have become accustomed to “governing by government” (Zhouxiang, 2017). Volunteer teams and public service groups are unable to communicate with residents in the community, enter the neighborhood office to communicate with staff, or coordinate the work of different departments.

(3) Market forces represented by designers and the private sector

In the process of updating the leftover space, on the one hand, developers still tend to take orders for large-scale projects instead of small projects like leftover space. On the other hand, the designer's information source is not sufficient. On this basis, the designer is not satisfied with the project itself and the entrusted income.

In the face of the above problems, information gaps between multiple parties have led to inefficient communication and unsatisfactory results. At present, some large cities in China have a certain foundation for the use and transformation of leftover space, but there is no deliberation.

3.2.2. The demand side (resident) opinions are not fully heard

The autonomy of the four types of participation increased in the following order (Table 1): mandatory participation, guided participation, spontaneous participation, and planned participation, and the impact on the formation of community communities was weak to strong (Yang Min, 2007). During the current period of leftover space renewal in China, public participation is still in its infancy stage, staying in the stage of mandatory participation or non-participation.

Participation content [□]		Participate in the decision making process [□]	
		NO [□]	YES [□]
Public issue [□]	YES [□]	Mandatory participation (welfare participation) [□]	Spontaneous participation (recreational participation) [□]
	NO [□]	Guided participation (voluntary participation) [□]	Programmatic participation (equity participation) [□]

Table 1. Types of Urban Community Residents Participating in Community Governance

Source: Yang Min. Community as a unit of national governance [J]. Sociological Research, 2007 (4).

It can be seen from the analysis above that in the process of renewing leftover space, each subject faces various problems, further deepening social inequality, information imbalance, resource/finance shortage, and causing various subjects to be unwilling to participate (Yamazaki,2019).

4 city 360

The general conclusions that can be drawn from the cases (1) the coordinated management of urban communities should promote the development of community non-profit organizations; (2) effectively enhance the participation of community residents; (3) broaden community governance Source of funding.

4.1. Project

Faced with this, we creatively proposed a full-process leftover space renewal plan--city 360(Figure 4) based on the core value of 360-degree repairing the city and created a knowledge sharing and business platform -- city 360 platform to provide services in the community. City 360 team has built a knowledge sharing and business platform -- city 360 platform to provide services in the community.

Figure 4. City 360-a democratic, multi-level planning tool and an innovative method

Source: Author

City 360 platform (Figure 5) has several prominent features, such as upload on the spot, design guidelines, database and product library. Using GIS technology, users can upload photos to the platform, submit transformation requirements in real time and make specific positioning. The team integrated to create the design guidelines of leftover space, from aspects of safety, green, vitality and wisdom, which the output design is based on. Database refers to a large number of design drawings, most of which come from the resource database of Tongji university. Through parameter screening, suitable schemes can be quickly found out. The product library is a collection of fabricated building fittings that the team researches and develops, which will be described later.

Figure 5. City 360 platform based on big data and artificial intelligence

Source: https://www.city-tech360.com/city360_web/

The platform, whose main forms are website and WeChat applet, can play a role in every stage of transformation. In the early stage of the renewing process, the platform can match the subjects of the leftover space renewal online, provides them with communication channels, and identifies the needs of the transformation. In the design stage, the introduction of artificial intelligence technology enables the realization of intelligent design. After several simple multiple-choice questions (Figure 6) finished, the platform can immediately output design drawings that meet users' requirements. During the bid evaluation stage, residents can vote on the proposal through the platform (Figure 7) In the later process of construction and use, each participant can also continuously supervise and track the transformation through the platform (Figure 8). City 360 did the following work.

With artificial intelligence, anyone can design their own distortion space

Artificial intelligence design

Using the artificial intelligence method to automatically design the scheme that Party A wants, the designer can directly design according to the design scheme of artificial intelligence to improve the design efficiency

Design your own deformed space transformation program

Select Distortion Space Size

How many times the existing space is distorted?

☐ Largest (100-200%)
 ☐ Medium (20-100%)
 ☐ Smallest (10-20%)

Select Distortion Space Form

What is the shape of the distorted space?

☐ Line
 ☐ Surface
 ☐ Solid

Select Distortion Space Properties

What is the main function of the distorted space?

☐ Commercial space
 ☐ Residential space
 ☐ Public space
 ☐ Office space
 ☐ Entertainment space

Choose the design service life

How long will the distorted space be used?

☐ Less than 10 years
 ☐ 10-20 years
 ☐ 20-30 years
 ☐ More than 30 years

Selecting zero space

How many zero spaces are there?

☐ None
 ☐ Several

Select Distortion Space Location

Where is the distorted space located?

☐ Urban Center
 ☐ Urban Edge Area
 ☐ Suburban Center
 ☐ Suburban Edge Area
 ☐ Rural Center
 ☐ Rural Edge Area
 ☐ Waterfront
 ☐ Airport
 ☐ Station
 ☐ Park
 ☐ School
 ☐ Hospital
 ☐ Government Office
 ☐ Religious Site
 ☐ Cultural Site
 ☐ Sports Site
 ☐ Industrial Site
 ☐ Commercial Site
 ☐ Residential Site
 ☐ Public Space
 ☐ Green Space
 ☐ Water Space
 ☐ Sky Space
 ☐ Underground Space
 ☐ Other

Select the environment where the distorted space is located

What is the surrounding environment of the distorted space?

☐ Natural Environment
 ☐ Urban Environment
 ☐ Rural Environment
 ☐ Other

Select the function needed to distort the space (multiple selection)

What is the function of the distorted space?

☐ Shopping
 ☐ Living
 ☐ Working
 ☐ Playing
 ☐ Learning
 ☐ Other

4.2. Project Innovation

(1) Full-process services

City 360 creates a full-process service on activating leftover space and proposes an innovative business model with reference value to the industry. City 360 will transform the entire process data and feedback data into the database, and continue to follow up on volunteer activities and internships in the space.

(2) Introducing artificial intelligence

Considering the cost limitation, time limit and professional limit of the leftover space modification, City 360 introduces artificial intelligence technology in the design process. Combining with the existing cases and using the structured processing, the method forms a self-contained database for machine learning, so as to realize an intelligent design process from the input of the transformation

scenario and the transformation requirement to the output transformation scenario, which brings more possibilities for leftover space.

(3) Assembled environmental protection modules

While providing full-process services for transformation, City 360 independently developed a number of building assembly molds (see Figure 9), materials and finished products for use in leftover space transformation.

Figure 9. Application of prefabricated building products

Source: Author

(4) Improving employment

City 360 creates a teaching application scene in the whole process of transformation, introduces college students into social practice, and helps college students understand the industry situation, cultivates the professional quality of college students, and promotes the goal of adapting college students' talents to meet social needs, thus improving the employment quality of college students.

(5) Multi-actors cooperation

The full-process service described by City 360 is actually an innovative cooperation system that conforms to "Government-Industry-University-Institute collaboration". It is a systematic cooperation of production, learning, scientific research and practical application by the government, users, enterprises, universities and scientific research institutions. (Lei Xiaoping *et.al*, 2012)

4.3. Multi-actors participation

4.3.1 Power balance

China is shifting from a "strong state-weak society" system to a "strong country-strong society strong market." As an auxiliary force, City 360's starting point is from a public welfare perspective. It mobilizes the enthusiasm of the corresponding stakeholders, maximizes the needs of all parties,

alleviates the conflicts of interests among the multiple subjects, realizes the coordinated management of the community in the three dimensions of government, society and market, and jointly strengthens community building and promotes the integration of community resources.

4.3.2 Cooperation between multi-actors

From the perspective of successful experience, the leftover space update mode has been transformed government independently responsible by the early period, into multi-actors collaboration between the government, community self-governing organizations and non-profit organizations. (Wang Chenghui, 2018)

The leftover space renewal involves multiple interest groups, such as government, street offices, designers, and local residents. These groups have different demands for space. (Xu Leiqing etc, 2017) City 360 acts as a non-profit organization to integrate multi-actors cooperation (Figure 10).

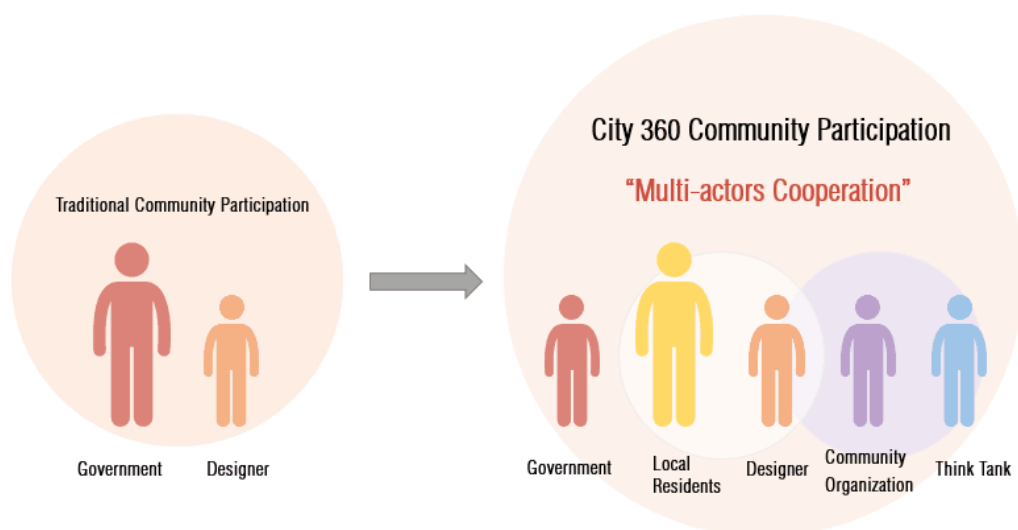

Figure 10. City 360 Community Participation

Source: Author

(1) National power

The City 360 team platform assists the grassroots city managers in contacting the designer team and checking the project, while this model can also introduce competition from the construction team to reduce costs. In this way, the city 360 team has played a very good role as the third party, allowing the grassroots government to get the desired design and service to the people in a short time and low cost.

(2) Social forces

The commonweal of the City 360 is not only reflected in the service of residents, the renewal of the city, but also in the platform of the university, serving on the students. The company team introduced the college student group into the role of “designer”. At present, the company has carried out a series of small-scale community renovation activities. On this basis, joining the strength of student volunteers will also help foster community self-governing organizations and foster volunteer organizations. At the same time, the platform also helps to create a teaching application scene, serving the teaching and research, and is highly praised by teachers and students (Figure 11).

Figure 11. Fosters community volunteer team to work with local residents in Xuhui, Shanghai

Source: Author

(3) Market forces

The City 360 can match the designers to the projects they want to do, and promote designer's work in the community to raise awareness, and get the opportunity to continue working with government agencies. In addition, through cost control, designers can also get a reasonable reward. It is a win-win situation for designers to improve their visibility and reduce costs while increasing visibility.

4.3.3 Resident satisfaction

Community residents are highly praised in the renewal of completed projects. At present, City 360 has realized the process from mandatory participation to guided participation, and is continuously implementing spontaneous participation of residents. Through the above series of simple and feasible methods, the team is not only strengthening the public participation awareness, so that they are willing to participate in the activities or affairs of the distortion of the space transformation, but also gradually exert their supervision role on the community public decision-making, to finally achieve the ultimate goal -- community autonomy (see Figure 12).

Figure 12. Spontaneous participation of local residents in Yangpu, Shanghai

Source: Author

5. Summary

City 360 promotes multi-actors integration in the whole process of leftover space renewal, ensuring the technical and economic rationality of project operation. The government can get out of the heavy project management. While reducing the financial burden for the government, the choice of designers and design teams is broadened. The whole process introduces college students to participate in the design, improve the practical skills of college students, and realize the integration of production and education. At the same time, the team assisted in the establishment of a residential hearing system to promote residents to become the main body of distortionary space transformation and urban governance. The city 360 team public welfare project is used as a carrier to stimulate the vitality of social organizations. Through this series of practices, the problem of proactive discovery is finally achieved, and the city is refined and intelligently managed (Figure 13).

City as a transformational tool. The infinity cities of Ivan Leonidov

Luca Lanini

DESTeC, University of Pisa, l.lanini@ing.unipi.it

Abstract: During late '20s and early 30's, the debate on the masterplan of Moscow, on its architecture as the capital of the Workers' Promised Land and, by extension, on the form of the new Socialist City (*Soc-gorod*) transformed this metropolis into the largest urban laboratory of the 20th century. Two were the main positions: "urbanists", such as Sabsovič, who still believe to achieve the formal control of the urban entity implementing industrialization, territorial planning and the *engineering of individual existences*; and "disurbanists", such as Okhitovič, who at the contrary conceived city as a superstructure of the bourgeois-capitalist modes of production, made obsolete by the Bolshevik revolution and that, as such, should be overturned. For "disurbanists", the collapse of the city inherited by Czarism should have been implemented by dissolving the city in a new territorial form, using to this purpose the new infrastructural network planned (or better dreamed...) by Soviet Power (cars, trains, airplanes, airships, spacecraft!). The city would no longer have a form but would have to be reduced into pure process, directly derived from the Kuzmin's "daily life program", defined by the distances for commuting to the production sites, designed by the sinusoidal diagrams of the circadian rhythms of workers and by the "industrialization" of their sleep-rest-works periods. The Socialist City is founded on a brand new dimension: its scale is related to the continental extension of the Soviet Union, to the horizon of the steppes, to the industrial compounds strategically dispersed all over the U.S.S.R territory. During the years 1928-30, Ivan Leonidov (1902-1959) conceived an idea of city sprawled across the entire Soviet Union: an *infinite* urban structure, innervated by industrial zones, residential compounds, public buildings, ready to colonize the whole nation. The goal was a city-nature hybrid, unlimited but endowed by the measure given by an orthogonal ribbon grid conceived as a geographical dimension rather than a geometrical form of urban planning. A *centuriatio* that potentially went from Moscow to the Urals, a *linear* disarticulation of the American Jeffersonian grid, an "all program and no form" plan - as Rem Koolhaas would say - that was tested in the competition design for the new industrial town of Magnitogorsk. Or, in an alternative version, Leonidov's city becomes a *network*: its nodes are institutional buildings whose distances are calculated on the basis of the power of the radio signals that connect them (project for the Social Club of a "new type" versions A and B).

Keywords: Ivan Leonidov, Constructivism, Socialist City, Soviet Architecture

Introduction

I would like to discuss the work of Ivan Leonidov in the context of his own time, his visions for a future for the city and the landscape (and the city *as* a landscape) of the Soviet Union. A future that seemed at hand, so far from the *leap forward* and the wellsonian science fiction of Krutikov¹, for example. A project for the future, at the same time so visionary and so prophetic that it still seems to be contemporary today.

Between 1927 and 1934, before his career would be so abruptly interrupted, Leonidov worked with great accuracy on buildings and urban designs that could have turned in architectures the transformations occurred in the Soviet Union: buildings as embryos of a New World that promised a different and more rewarding way of life (*byt*) for both the working class and the Soviet establishment.

¹ Georgii Krutikov (1899-1958) was a Soviet architect who famously designed Flying Cities orbiting around Earth and connected by single seat astro-planes.

For Leonidov, buildings and city are conceived as great *transformative tools* of the individuals and society (and of society through individuals...) and this mutation takes place through absolute and pure architectural forms. Forms and spaces of architecture as a technical aspect: scrutinized not only for the resolution of the very serious contingent problems that also afflicted the *homo sovieticus* (as *kommunal'ka*, the forced cohabitation of several families in the same apartment, mass literacy, sanitation of urban areas, supply of infrastructures and services, anthropization of an immense territory), but by means of a new definition of physical and relational structure, with the aim to reorganize work, daily life, education, rest, city and nature.

In few, famous projects, Leonidov operated a radical rewriting of functional programs and therefore of the space of buildings (and of the space between buildings) which is still avant-garde today. He was guided by the faith in architecture and by a sort of an exterior light (a humanitarian socialism, "hedonist" and planetary? The beauty embedded in the motion of the Universe? The principle of "art as a construction of life"?) to conceive the composition and the daily functioning of these architectures. Like any *exalted rationalist*², Leonidov worked to overcome the conventions, even those that have settled in the few years in which Modern Architecture has been already operating in its Functionalist format.

Leonidov's projects are *objects of fantastic reaction* (Quilici, 1975), visionary but rigorous architectural machines, defined with great typological, distributive, constructive and urban precision [Figure 1]. His radical architectural program is mainly achieved by the means of Technique, constantly displayed in his designs.

Figure 1, Ivan Leonidov, House of Industry, 1928

After 1917 Technique is the conceptual tool chosen by the Bolsheviks to redeem the destiny of Great Russia and to transform it into an global industrial power. It is considered as a banner for the libertarian implications they saw in it ("the liberation of work") and it becomes the formal language of this

² For a definition of *Exalted Rationalism*, see Rossi A., 1967, Introduzione a Boullée. In: Boullée E.L., *Architettura. Saggio sull'arte* (Padova, Ita: Marsilio), 7-24.

"mystical" phase of the revolution. It is intended as an instrument for agitation and propaganda, a vehicle for information and calls to arms, a raw product for artistic experiments: the agit-prop trains, the posters and photography of Rodčenko, the cinema of Ejzenštejn and Vertov, the walking megaphones of Klutis, the huge urban installations of El Lissitzky and Tatlin, the people's theater of Mejerchol'd, the experimentation on language of Majakovsky. The first generation of Constructivists architects - the Vesnin³ brothers, for example - maintained a 19th century idolatry for Technique, a reminiscence of an industrial century that this extreme part of Europe has never known. For Leonidov, on the other hand, Technique is never just a constructive effort or adornment for a Socialist heraldry, but is a defining point of view on architecture. The collimation between compositional and constructive techniques is the way to completely redefine the relationship between purpose and form of buildings, between their meaning and the life of men, between architecture and city. A relationship between architectural composition and technology, between formal experimentation and the technical level of the Soviet construction industry that remained unresolved, and that would be later the main cause of the prompt eclipse of the avant-garde party in the Soviet architecture, of its implosion under the weight of the demands of the forced industrialization and the command that architecture must serve solely as assembly line in the construction of Socialism.

Leonidov's point of view stands in antithesis both to the formalism of the avant-garde and to the socialist realism, which basically converged on one point: the liberation of the arts from capitalist superstructures to make them immediately understandable by the masses. In Leonidov the research on abstraction and on the functioning, in many ways still unknown, of *new buildings for a mass society* generate a broader conceptual depth that does not allow us to select only formal aspects to the detriment of ideological reasons. Leonidov, who during his career will realize only one project, produced a series of architectural and urban designs of such paradoxical realism to be able not only to become the iconological heritage of every Modernism but also to trigger a debate that continues today on the transformation for the city of Moscow as well as for any other contemporary metropolis.

The city of steel

Moscow becomes the new capital of the Union of Russian Federal Republics on March 5, 1918, a decision whose strategic objective is to move the main government offices from the maneuvering area of White Armies. The city immediately became the point of accumulation of the main avant-garde groups that, having abandoned the Petersburg orbit, began to gravitate around some institutions like the VChUTEMAS and the InChuK⁴, real incubators of a production that ranges from cinema to photography, to the production of everyday objects, to graphics, to painting, to architecture, in the wake of the Bauhaus, just founded the year before in Weimar.

The city that emerged from the "war communism" (1918-1921) is an immense shattered village, a city of wood rather than stone with still strongly rural features: a monumental center, which has its symbolic focus in the fortified citadel of the Kremlin, then the vestiges of orthodox power, some *Modern* buildings (*Modern* is the regional variant of *Art Nouveau*), the production complexes, expelled towards the radial routes of the city, in the midst of a boundless village of wooden *isbas*. A metropolis where the epic of the capital of a new world must be built, made possible by the embryonic accumulation of urban capital and the repopulation generated by the *Novaja Ekonomičeskaja Politika* (New Economic Policy, NEP): it is the *transition city*, between *ancien régime* and Socialism (De Magistris, 1988). If during the years of the "war communism" Moscow had become a gigantic and temporary theater of shambolic urban scenographies, the NEP years saw the making of a whole series of new metropolitan centralities, a widespread network of buildings that must represent the tangible and daily symbols of Bolshevik modernization through the collectivization of culture. These *ganglia* of the Soviet establishment draw a new topography of power that overlapped with the ones inherited from Czarism. The mystique of the "capital of Socialism" is built either through the monumentalization of localized

³ Alexander (1883-1959), Leonid (1880-1933) and Viktor (1882-1959) Vesnin were among the most influential architects of the first wave of Russian avant-garde.

⁴ VChUTEMAS are the State Superior Arts and Technics Workshops founded in 1920 in Moscow, InChuK is the Institute of Artistic Culture founded by Vassilij Kandinskij in the same year.

urban junctions (clubs, for instance), or through large complexes (*ansambl'*) that mixed infrastructural nodes and bureaucratic institutions, appearing as colossal propaganda and symbolic machines. These dense complexes on a metropolitan scale must be immediately recognizable, visible from every part of the city, incarnating the image of the power and the "weight of the State". The skyline of the capital becomes a precise technical question many architects like Ivan Leonidov, Alexander Vesnin and El Lissitzky⁵ dealt with.

The dazzling revolutionary Moscow of the NEP is the theater and the field of forces within Leonidov organizes objective data and give them form through peremptory architectures actively working to expand the material and psychic dimension of the metropolis and to draw it on another scale, the territorial one, necessary to weld countryside and large productive entities to the destiny of the city.

Leonidov correctly identifies in this overlap, physical rather than ideological, the only possibility of survival of the Soviet collectivist utopia: the city as "a sublimated acropolis" of countryside made productive by industrialization.

This is the meaning of the colossal dimensions of the Lenin Institute [Figure 2], of the Narkomtjažprom complex, of the Palace of Culture of the Proletarsky district, of the plan for Magnitogorsk. The architecture becomes, together with the airships, the airplanes, the flying machines of Krutikov, the Tatlin's *Letatlin*⁶, the tool to fill this *big emptiness*, to fill the space of Soviet Russia with a new civilization. The city is therefore transformed into a potentially infinite artifact and its space in a void furrowed by the orbits of buildings that with absolute geometric shapes measure the Earth's surface and define the space-time continuum (which therefore excludes the pre-Einsteinian and premodern distinction between interior and external spaces) of environments for residence, for education, for physical education, for the continuous training of the individual through work.

Figure 2, Ivan Leonidov, Lenin Institute, 1927

Architecture for a New World

The architecture of worker's club is therefore one of the cornerstones of the design reflection of Leonidov (as well as of the others Constructivist architects). They are the *social condenser*, the palaces of the new ruling class, the "aristocrats of proletariat." In 1928 Leonidov designed two futuristic projects for a "new type" clubs (version A and B). The intersection of activity required by this new ganglion of

⁵ Lazar El Lissitzky (1890-1941) was one of the major modernist artist, actively working as painter, sculptor, graphic designer and architect in Russia, Switzerland and Germany.

⁶ The *Letatlin* is a human powered flying machine invented by the Soviet artist Vladimir Tatlin (1885-1953).

the socialist society cannot be confined to a single building (as it happened in Melnikov's⁷ or Golosov's⁸ work), but becomes a *pavillion* system (a memory of the native village?) including vast areas of industrially cultivated land, botanical gardens, zoos, laboratories for scientific research, sports and outdoor communal equipments, mass theaters, airports, gigantic television screens (he also invented a term - *televizde* - in 1928!) that broadcast newsreels and films, amplification systems that do not transmit music but fragments of discourses and background noises, in a surprising anticipation of both the *musique concrète* and the *found voices* of Eno and Byrne [Figure 3].

Figure 3, Ivan Leonidov, Social Club of New Type version a9, 1930

The buildings around which the landscape design revolves are large ogival glazed structures that clearly looked at the Moscow Planetarium designed by Baršč and Sinjavskij⁹ in 1927, within which flexible spaces are organized to host conferences, politics meetings, scientific demonstrations, libraries, swimming pools, gyms, greenhouses. The club has become a widespread system for a rarefied, territorial city, in which spatial relations have dissolved into a new perceptive and psychic paradigm placed between phenomenal spaces and diagrams and which aims at “a general reorganization of consciousness”. A new city, sparse but large as the whole country, connected by an *immaterial infrastructure*: a net of radio receivers in a sort of precognition of what a *smart city* is: “Each building appears as a node that bears significance equal to its potential for cultural dissemination and reception. The curves of the diagram identify cultural centers with transmitters of electro-magnetic signals, suggesting that Leonidov understood culture – or cultural organization – as no longer a problem of

⁷ Konstantin Melnikov (1890-1974) was one of the most famous Constructivist architect, he designed several masterpieces as the U.S.S.R pavillon at the Paris Exposition of decorative Art in 1925.

⁸ Ilja Golosov (1883-1945) was a Soviet architect of the first Constructivist wave, author of the famous Zuev Club in Moscow in 1928.

⁹ Mikahil Baršč (1904-1976) and Mikahil Sinjavskij (1895-1974) were both Constructivist architects.

absolute space and distance, but rather as a function of signal strength. The points in Leonidov's diagram elide the difference between the club as material architecture and the club as site of immaterial media exchange. [...]. With his club, Leonidov sought to embed Soviet culture within a new logic of social, spatial and media relations. In doing so, he articulated a distinct position within architectural constructivism, one that addressed not the organization of material and space but rather the organization of media networks and their spatial consequences" (Anderson,2013) [Figure 4].

Figure 4, Ivan Leonidov, Social Club of New Type, 1930

But even those lush, abstract systems in which architecture is constricted are never self-referential objects, they are deformed by the links with the other urban facts they intercept: the Palace of Culture of the Proletarsky district and its planimetric grid rotates to accommodate in the lay-out the ancient Simonov Monastery, the Lenin Institute finds its alignment in one of the Muscovite radials, the Narkomtjažprom (Minister of Heavy Industry) weaves a series of almost musical relations with the positions and proportions of the monuments that gather inside and around the Kremlin citadel. The Palace of Culture is a part (the origin?) of an infinite city that ranges from Moscow to the Urals. It is basically a *superclub*, it has accesses to a range of technologies producing a sensorial experience equal to that of a contemporary rock show: lights, over-amplified sounds, cut-up images on giant screens, rotating stages, bridge, cranes, mobile walkways, all props taken from the research of the Futurists and the Productivists for the stagecraft during the first years of the Revolution [Figure 5].

Figure 5, Ivan Leonidov, Palace of Culture of the Proletarsky district, 1930

The complex is located in a large lot in the southern suburbs of Moscow, occupied in part by the Simonov monastery, which Leonidov doubles and divides into four consecutive squares of 240 m side, each organized around a building that determines its use. A pyramid is the sport building: a large gym, a swimming pool with an artificial beach, gardens and terraces for heliotherapy. A semisphere shaped in iron and glass acts as an auditorium for mass manifestations. It is the anti-Bolshoi, as stated in the liner notes accompanying this projects: thanks to the variable configuration of the slabs and the seats as already experimented in the Total Theater by Gropius and Piscator (1929) and in the building designed by Mejerchol'd and Barkhin¹⁰ (1930). A giant truss serves as a mooring for airships and a radio mast, a long bar on *pilotis* is designed to accommodate scientific laboratories and a library [Figure 6].

Figure 6, Ivan Leonidov, Palace of Culture of the Proletarsky district, 1930

¹⁰ Grigorij Barkhin (1880-1969) was a Soviet architect, famously working with the theater author Vsevolod Mejerchol'd for an experimental theater in Moscow in 1930-33

It is a rarefied system of buildings, yet another composition of Platonic solids, whose innovative conception has remained intact. His program already included food and energy self-sufficiency, the continuous view of avant-garde films, educational documentaries, newsreels, sports commentaries which were to replace the folk dances and classical ballets, military songs and hymns of the *kolchozij* in the training of Soviet citizens. Connections are ensured by aircraft, the only means of moving in the immense Soviet country, education is based not so much on the great Russian literary tradition, but on scientific-technological training and physical education, on the pragmatic productive use, almost in a physiocratic way, of the land, that is a fundamental part in the composition of this complex.

The infinite city

If the Russian avant-garde was able to design the many utopian variations of the Socialist City it was also always able to propose pragmatic and progressive alternatives to the problems of the real city.

The "war communism" has depopulated the capital (almost halving its population) and left its building stock and infrastructures in a state of obvious degradation. During the NEP the condition of overpopulation that had characterized the last Czarist phase took its toll. The debate on the urban figure, the *grosseforme*, of Moscow and its architecture and, by extension, those of the new Socialist City transform this metropolis into the greatest urban laboratory of the twentieth century.

For "disurbanists", such as Okhitovič¹¹, the city as we know it is a superstructure of bourgeois-capitalist modes of production which should be demolished. It will no longer have a shape but will be reduced to a pure process, which arises from the "graph of daily life" elaborated by Kuzmin, from the sinusoidal diagrams of the circadian rhythms of workers, the distances for commuting to the places of production and the "industrialization of rest", such as the SONnaja SONata, the Melnikov's "sleep factory" or the holiday resorts of Sokolov¹².

A principle gathered from the 1930 project for the "Green City" of OSA, coordinated by Ginzburg¹³ and Baršč. The objective is the *destruction* of Moscow: decentralization of all production complexes, deportation of the entire population along the axes connecting the capital to the new industrial towns, prohibition of building within the urban perimeter, demolition of unhealthy neighborhoods, transformation in equipped parks of all the free areas available, reorganization of the 17th century Moscow in a gigantic theme park in which some duly isolated monumental ensembles emerge (the Kremlin, the Arbat, etc.) as well as new collective complexes dedicated to culture, rest and research.

If the Capitalist City is the urban formalization of relations of productions rendered obsolete by the Bolshevik revolution, the Socialist City cannot take back either its axes or its forming modalities, it must indeed overturn them. Starting from the relationship between nature and buildings, up to a general rethinking of its dimension which has to deal with, in order, the continental extension of the Soviet Union, the new infrastructural level, the production units strategically scattered from Leningrad to Vladivostok.

In Leonidov's work the real city (Moscow, Magnitogorsk) and the planned one overlap: the first is not only a scenographic background, the second is not only a design, together they are a unique dialectical reality equipped by the new architecture and whose material is an *expanded void* that seems to aspire to a cosmic dimension, that "space as a non-material coagulant" (Quilici, 1975). An avant-garde point of view on architecture and city pursued through the use of all modern techniques related to transport, communication, image, construction, composition.

In Ivan Leonidov's vision, Moscow becomes the nucleus of the celebratory centers of the administrative buildings in which the Soviet power is articulated (great isolated complexes, ancient and modern: the Kremlin, but also the ministries, the Palace of Soviets, the headquarters of the great cultural institutions),

¹¹ Mikahil Okhitovič (1896-1937) was a Soviet sociologist and urbanist who led the current of disurbanists. Executed by NKVD during the Great Purgue.

¹² Nicolai Sokolov (1904-1990) was a Soviet architect. He designed the socialist version of SPAs and holiday communal resorts.

¹³ Moisej Ginzburg (1892-1941) was a Soviet architect, one of the masters of Russian Constructivist. He designed one of its famous building, the communal house NARKORFIM in Moscow in 1928-32.

from which an infinite, ribbon-like urban structure, innervated by industrial areas, residential neighborhoods, public buildings, prolonged itself throughout the Soviet Union, colonizing that boundless territory.

The objective is a city-nature, unlimited but endowed by the measure given by a *centuriation*: a geographical dimension rather than a geometrical-urban pattern. A system that potentially goes from Moscow to the Urals, a linear disarticulation of the Jeffersonian grid, a "all program and no form" plan - as Koolhaas would say - which is concretely tested in the design for the new mining town of Magnitogorsk [Figure 7].

Figure 7, Ivan Leonidov, Plan for Magnitogorsk, 1930

A competition – won by the May Brigade, the group led by the former Frankfurt chief architect - in which the various trends operating in the USSR on the project of the *Sov-Ggorod*, the new socialist city, confronted themselves. Leonidov proposed an organization based on the repetition of large square meshes equipped with large collective buildings, industrial centers, towers for apartments and low houses. Even for these lodgings the principle of the collective housing is enforced: small cubicles for individual rest that converge in a large collective environment equipped with tea rooms, gardens, spaces for physical exercise. A libertarian, pre-hippie commune rather than a *Dom Kommuna*, a less militarized version of the contemporary experiments on the residence of STROIKOM (Building Commission of the Russian Republic) led by Moisej Ginzburg.

Ensuring an advanced level of housing is one of the main objectives of all the researches on architecture and the city of the first Soviet era. For Ivan Leonidov, before being a "living machine", the house is an exact device for the construction of a new life: it must allow individual rest and at the same time maximize the moments of collective life; must have the necessary intimacy for people forced into years of *kommunal'ka* and at the same time be the first cell of collective organization of society (a "laboratory of communism"); it must be recognized as a home by the recently urbanized masses and also have all the comforts of bourgeois residences; it must be technologically advanced but also economic and buildable in a short time by unskilled workers, it's a tool that can transform the worker of a Communist state into a "new man", built to allow the transition from a bourgeois way of life to a socialist one, which in this most extreme examples presupposes the dissolution of the family and the collective care of children [Figure 8].

Figure 8, Ivan Leonidov, Plan for Magnitogorsk, 1930

But it is on this ideological issue that the main failure of Soviet radical architecture (and of the Soviet system) is consummated: the nation born from the October Revolution is not able to produce a significant discontinuity to the housing crisis of the Czarist era, even when its masters produces some significant prototypes.

Those buildings and programs for Moscow designed by the Soviet avant-garde at the turn of the 20s and 30s of the 20th century seem to return continually, almost subliminally, to the fabric of our daily experience. Russian vanguards have spread their effects throughout the 20th century and are prolonging their extraordinary fascination even in the new one. Especially from the point of view of architectural and urban design. It could be useful to reflect on how some great contemporary urban landmarks have introjected some icons of the Constructivist period. In London, for instance, where Renzo Piano's Shard is modeled on a section of a Leonidov project, while Anish Kapoor's Orbit Tower is a clear tribute to Tatlin's Monument to Third International. Architectures that have not been able to build Moscow as the capital of the Soviet Nation and instead return to build other cities, as has often happened in urban history for buildings of such symbolic and evocative power.

A collection of projects that gives us the image of an *alternative* Moscow, of a great collective project for the construction of the city and its architecture once confined to the world of urban visions but capable of configuring - from their architectural figure to their historiographical "aura" - a plan for a "analogue Moscow", transforming it into a modern and cosmopolitan metropolis, while recording the dramatic changes in Russian history of which it was the theater.

Reflecting on these projects means guessing how Moscow would have changed, in its morphological features, in its urban dimension if, in one of the many sliding doors of history, it had been built by the vanguards and not by the realsocialist classicism that redesigned its vast sectors in the following years. A process of alternative construction of the city which actually, though in a latent form, has always been in place, because the architectures of Leonidov, Lissitsky, Mel'nikov, the Vesnin brothers had clearly predicted axes, themes and issues that the development of this great Eurasian metropolis would eventually have ended up facing in the following hundred years.

As if they were architectures so meaningful that somehow managed to deform space and time.

Abstract: The main social contradictions in China have been transformed into the contradiction between the people's growing need for a better life and the unbalanced and inadequate development. Citizen engagement on planning and design need to be boarder and deeper. Introverted, "top-down" ways are transforming into more open, communicative and participative approaches. In the making of CFC process, Changsha has gradually explored a set of method and tools in multi-level planning and design, which embeds communication and participation into three-levels: macro, meso and micro. Planning and design now pay more attention to each individual citizen in the city than to the abstract population indicators in the past. It is becoming a more open and democratic process, so that citizens have more ways of communication and participation. This paper hopes Changsha experience will be helpful to more communicative and participatory planning and design in the future.

Keywords: Participatory planning, Children friendly city, Changsha

1. Introduction

President Xi Jinping pointed out in the report of the 19th National Congress of the Communist Party of China (CPC): "As socialism with Chinese characteristics enters a new era, the main contradictions in our society have been transformed into the contradictions between the people's growing need for a better life and the unbalanced and inadequate development." The unit of Chinese society is family, in which children plays a central role. Many families' needs for a better life revolve around children. With the increasing level of urbanization, more and more Chinese families live in urban environment. Whether the city is "child-friendly" directly affects the life of every family, and is closely related to the "sense of happiness" and "sense of acquisition" of people.

In 1989, the Convention on the Rights of the Child was promulgated, which proposed that "children's rights" should be the core element of urban development. In 1996, UNICEF and UN-Habitat jointly proposed the International Child-Friendly Cities Initiative (CFCI), which integrates children's needs into urban planning and becomes an important guiding document for the creation of child-friendly cities. Since the launch of CFCI, more than 870 cities around the world, including London, Seattle, Copenhagen and Buenos Aires, have been certified by the International Secretariat of Child Friendly Cities by 2015.

At present, China is at the initial stage of the child-friendly city making. Increasing numbers of cities in China have begun to explore creation of child-friendly city, such as Beijing, Nanjing, Shenzhen,

Hangzhou and etc., as seen in Figure 1. In 2016, Changsha launched the creation of child-friendly city in an all-round way. Taking this as an opportunity, Changsha city improves the overall quality of urban living environment and attempts to construct integrated mechanism of reaching consensus, co-construction and Co-governance of government, community and the market. Changsha's child-friendly city creation aims to make the urban built environment more "temperate", urban governance more "people-oriented", and people's "sense of happiness" and "sense of acquisition" be comprehensively enhanced.

Public participation in urban planning has become an important part of urban planning development in western society since the mid-1960s. Public participation in urban planning is regarded as a basic right of citizens. In the process of urban planning, it is necessary to involve the broad masses of urban citizens, especially those affected by the planning content, in the preparation, discussion and decision-making process. Planning departments must listen to various opinions, and reflect them as much as possible in planning process and planning action. A truly comprehensive and complete public participation requires that the public be truly involved in the decision-making process of planning (Arnstein, 1969).

In the context of the overall transformation of the domestic society in China, urban planning communication and participation are also becoming an important part of urban planning development. Taking Changsha Children Friendly City as an example, this paper reflects the current situation of participatory planning in China, provides references for more urban communication-participatory planning, design and action, discusses and exchanges with international urban planning experience.

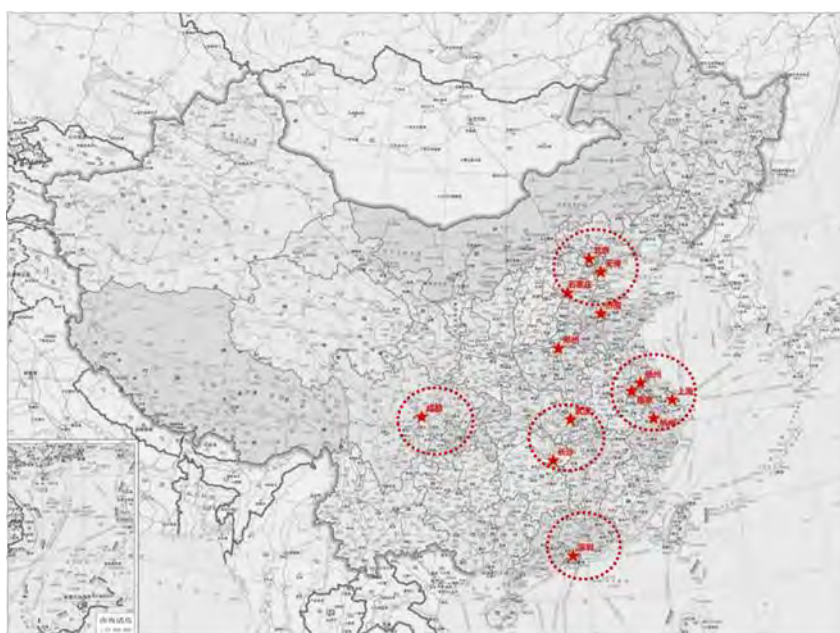

Figure 1 Chinese Cities in making of "Children-Friendly-City"

2. Children-Friendly-City making: Changsha's pattern

In the context of China, government, as the leading force of society, play an important role in guiding urban development. In the process of Children-Friendly-City making in Changsha, government also plays a leading role in initiation and organization.

Children-Friendly-City (CFC) making in Changsha is with characteristics of multi-dimension, multi-subject and multi-level.

(1) Multi-dimension: policy friendliness, space friendliness and service friendliness. Each dimension corresponds to a number of thematic actions, and each action contains a series of specific tasks.

(2) Multi-subject: creating a children-centered, integrated government, social institutions, communities, schools and families joint force, and establish a child-friendly "children plus" governance and service system.

(3) Multi-level: led by planning department, to create a multi-level planning system incorporating Children-Friendly goals, with introduce citizens (especially children) into planning and design actions at macro, medium and micro levels to communicate and participate into the overall process.

2.1 Multidimensional Children-Friendly Action

Children-Friendly-City (CFC) making in Changsha covers three dimensions: policy friendliness, space friendliness and service friendliness. The three dimensions correspond to a number of thematic actions, each of which contains a number of specific tasks. As seen in Table 1, Figure 2.

Policy friendliness is implemented in three aspects: urban strategy, policy evaluation and formulation, and child participation. Urban strategy refers to Changsha's declaration of Children-Friendly-City to the United Nations, which is an initiation to lead all aspects of CFC making activities.

Space friendliness is implemented in four aspects: demonstrate space system, education space system, living space system and traveling space system. The experiment and demonstration of children-friendly space system are carried out on the scale of urban and block space system, which contains "one demonstrate city area" and "two demonstrate blocks".

Service friendliness is implemented in three aspects: children's social welfare guarantee, public education service guarantee and children's friendly propaganda and promotion. The three actions correspond to health, education and culture respectively. Children-friendly cities not only attach importance to the shaping of physical space, but also pay more attention to all aspects of children's urban life, which are aimed to fully guaranteed and promoted.

Table 1 Action Plan for Changsha CFC making (2018-2020)

3 Dimensions	10 Themed Actions	40 Tasks
Policy friendly	CFC Creation Action	1. CFC Action Plan Framework; 2. CFC Declaration
	CFC Policy-making Action	1. Research on supervisory evaluation system; 2. Analysis of children's rights and interests 3. Guidelines for the design of CFC Space
	CFC Participation Action	1. Children's Conference Training; 2. Children's Friendly Logo Design; 3. Developing Children's Tour Map; 4. Children's Participation Framework
Space friendly	CFC Demonstration System Action	1. To Build a Demonstration District; 2. To Build Two Demonstration Blocks
	CFC Education Space Action	1. To Make 12 CFC Schools and Promote; 2. Kindergartens' Special Planning; 3. Compile Changsha Research Practice Map and Children's Contact Book; 4. CFC Reading Space Demonstration and Promotion
	CFC Living Space Action	1. CFC Parks Pilot and Promotion; 2. To Create CFC 15-minute Living Circle; 3. To establish 200 Maternity Room; 4. CFC Public Space Demonstration and Promotion
	CFC Traveling Space Action	1. To make 50 love & care zebra crossing line; 2. improve children's safety alarm system; 3. purify surrounding environment of the campuses; 4. establish CFC community protection mechanism; 5. CFC school path demonstration and promotion
Service friendly	CFC Welfare Action	1. Improve children's vaccines supervision and service systems; 2. Optimize children's health care resources; 3. Improve children's medical security level; 4. Improve protection mechanism for vulnerable children; 5. Strengthen child health care services and management; 6. Improve children's nutritional status ; 7. Establish community centers for women and children; 8. Promote child-friendly Enterprises
	CFC Education Action	1. Guarantee Children's Equal Right to Education; 2. Optimize the Internal and External Environment for Children Learning and Growth
	CFC Propaganda Action	1. CFC Promotion Action Framework; 2. Children Safety Guardianship Plan; 3. Initiative of Creating Child Friendship Cities; 4. Multi-dimensional Promotion of Children Friendship Cities; 5. Child Rights Protection Knowledge Training and Legal Promotion

Figure 2 Framework of Vertical and Horizontal Coordination Model

2.2 "Children +" Governance and Service System

The construction of child-friendly city needs not only the government's advocacy and organization, but also the formation of a multi-governance service system of multiple social subjects. In the process of building a child-friendly city, Changsha formed a "children plus" governance service system, which takes children as the center and integrates five main parts as government, community, family, school and institution. As seen in Figure 3.

The refinement and implementation of tasks in themed actions require the coordination and cooperation of government departments in horizontal and vertical way.

Horizontal cooperation reflects in the actions led by specific department and collaborated with the relevant. For example, the Municipal Education Bureau is in charge of policy-friendly action; the Municipal Planning Bureau is in charge of space-friendly action; the Municipal Women's Federation is in charge of service-friendly action; and the Ministry of Propaganda is in charge of news and press.

Vertical coordination reflects in the transfer of responsibility from municipal government level to district and county government level. The implementation of district and county, street and neighborhood committees is deepened and refined layer by layer.

The vertical and horizontal division of responsibilities of government departments was clearly and publicly stated in the Declaration Plan and Three-year Action Plan for Children-Friendly Cities of Changsha (2018-2020).

Figure 3 "Children +" Governance and Service System Framework

2.3 Planning System Incorporating Children-Friendly Goals

In the Children-Friendly-City (CFC) making in Changsha, the planning department took the lead role in implementing the concept of children-friendly at all levels, in order to achieve "space-friendly" at spatial level. The multi-level planning with goals of "child friendliness" and "space friendliness" firstly dismantle the overall goal from the macro, medium and micro levels, and then implement the specific objectives at the corresponding levels. As seen in Table 2.

At the macro level, the first step is to reach a consensus on the "children-friendly" value, which is the basis of public policy formulation, so as to facilitate integration of children-friendly-related public policies into planning system. The related planning documents involves Changsha 2050 Strategic Plan and Changsha City Master Plan (2017-2035).

The two plans are with their own emphasis. In the process of compiling the Strategic Plan, a variety of public participation activities have been carried out, especially in children-friendly city and senior-friendly city special reports. "Happy Community Action" has become one of the eight key actions in short term. In Changsha City Master Plan (2017-2035), a strategic transmission system of "Goal-Strategy-Indicator-Action" is constructed. The strategy of "creating a friendly city for children and the elderlies" is one of the "better home" strategic objectives.

At the medium level, contents in the macro-level planning are linked up and deepened. Specific goals are to implement the planning facilities allocation, with care for children, elderly, disabled and other vulnerable groups, and enhance the "sense of gain" of people, Such as the "15-minute life circle planning", "kindergarten and schools special planning" and etc. Plans set conceptual indicators, such as the "15-minute life circle planning" proposed that "400 15-minute life circles should be delineated in city central zones", "primary schools/kindergartens should be included in the necessary matching projects, within 2 years basically meet the requirements for each living circle, and it is included in the performance appraisal task of district and county governments and departments.

At the micro level, it undertakes the upper level plans and implements strategies into the built environment. The micro level goal is to improve spatial environment, as well as to construct effective participatory methods and a fair benefit distribution mechanism on spatial level. Involved Specific plans and design actions include "pilot micro-renewal of children-friendly school districts", "design competition for child-friendly micro-space renovation", "love & care zebra crossing belt" (children's safe travel facilities upgrade) and etc.

In Changsha Children-Friendly City Declaration Plan and Three-Year Plan of Action (2018-2020), the dimension of spatial friendliness has launched four thematic actions, respectively aiming at children-friendly demonstrative space, children's education space, children's living space and children's traveling space:

(1) The children-friendly demonstrative space action includes six specific tasks, including the construction of the child-friendly demonstrative district, the construction of the demonstrative blocks, the promotion of the children-friendly communities citywide, the construction of the 20 demonstrative schools, the construction of the demonstrative parks and the construction of the children-friendly reading spaces.

(2) The children-friendly education space action includes the special kindergarten plan, the children's urban research practice map and children themed address book.

(3) The children-friendly living space action includes building children's 15-minute life circle, achieving 100 maternity care rooms, child-friendly SNS platforms and community (village) women and children's centers.

(4) The children-friendly traveling space actions include: completing 50 schools' "love & care zebra crossing belt", improving children's safety alarm system, purifying school surrounding environment, and building children-friendly school paths.

Table 2 Planning System Incorporating Children-Friendly Goals

Multilayers	Goals	Realated Plans
Macro-level	To reach a consensus on the value of "child friendliness". To become the basis of public policy making, and integrate into the planning system.	Changsha 2050 strategic Plan
		Changsha Master Plan (2017-2035)
Medium-Level	Implementing the allocation of facilities. Caring for children, the elderly, the disabled and other vulnerable groups. Enhancing the "sense of acquisition" of citizen life.	Planning and Construction of 15 Minutes Life Circle
		Special Planning for Kindergartens and Schools
Micro-level	Create humanized built environment. Forming participatory planning methods. Improving the mechanism of spatial benefit distribution.	Pilot Micro-Renewal of CFC Campuses
		CFC Micro-space Renovation Design Competition
		Love & Care Zebra Crossing Lines

3. Children's Communication and Participation in Multi-level Urban Planning, Design and Action: Changsha's Experience

In Changsha experience in children-friendly city making, every link is inseparable between the multi-subjects of society and government departments. Communities, families, schools and institutions are not only the "acceptors" and "responders" of government policies, but also the "actors", "organizers" and "direct beneficiaries" of specific events. Communication and participation are not only goals at all levels, but also the key way to achieve them.

3.1 Macro-level

At macro level, in the stage of reaching value consensus and laying down basic goals for public policy, the government departments led to carry out the "up-down linkage" action strategy to combine the upper design with the bottom action. As seen in Figure 4, Figure 5.

In the part of upper design, government directly increases opportunities of opening and communicating with the citizens in the policy formulation process; in the part of lower action, the city's media industry expertise has brought into play, and the planning authorities, cooperated with

relevant departments, organize a series of urban activities in which the citizens could be enrolled in, and take the activities as the carrier to enhance the public participation, awareness and sense of identity. The concept of children-friendly has been paid attention to in the early stage of making plans, and the communication and participation mechanism has been implemented into the policy making process.

In the upper design, planning authorities took the lead in compiling Changsha 2050 Strategic Plan and Changsha City Master Plan (2017-2035), which provided the overall framework of children's friendly value consensus from a policy perspective. Planners go deep into urban public venues, and disperse online and offline questionnaires, make interviews, host symposiums and other forms of public opinion surveys. Those contents provide plans solid and credible basis.

For example, in Citizen-oriented "2035. My Dream in Changsha", "Golden Idea" Collection for Changsha Master Plan, 170 proposals from citizens were received, covering strategies for urban development, community and public services, and etc. The first prize of the individual group came from a clerk of Changsha Local Chronicle Office. According to the nature of his work, he puts forward a plan with rich cultural characteristics of the city.

The periodical results of the planning are publicized through Internet, and the city planning exhibition hall is taken as a carrier, to integrate the expert discussion part into the "urban open course" for the public. The activities expand the two-way communication between managers and experts into the dimension of social openness. Open class introduce Q&A session, so that the citizens could participate in dialogues with experts and the government.

Through participation and dialogues, citizens could better understand the process and connotation of planning. It also promotes the government to get more feedback from the public in the early stage of the planning framework formation.

At bottom level, the planning department jointly organizes social activities horizontally with government departments and agencies, relying on various forms of organizational committees.

For example, activities such as "Discovery of Star City", "Children Friendly City LOGO Design Competition" (Children's Independent Design, Designer Collaboration), "World Children's Day", "Children's Tour Map Workshop" and a TV program "Playful City" with children as the main participant.

Contents of activities is centered on the city theme. On the one hand, collecting public opinions through the activities constitutes an important part in the compilation of the master plan. On the other, through the activities to enhance public awareness, understanding and participation, the platform mechanism of communication and participation is constructed.

The "Discovery of Star City" campaign for teenagers in the whole city was co-sponsored by Hunan Daily Newspaper Group and Hunan Provincial Committee of the Communist Youth League, Changsha Urban and Rural Planning Bureau, Hunan Daily News Training Center and Changsha Municipal Committee of the Communist Youth League, and sponsored by the Organizing Committee of Little Journalists of Hunan Daily. Activities are not only an important part of public participation in

the preparation of Changsha General Plan, but also one of the actions of Changsha to create a child-friendly city.

In 2018, "Discovery of Star City" provides a platform for primary and secondary school students to know about Changsha city, to understand Changsha and participate in the future urban planning of Changsha.

Under guidance, about 700 "young urban planners" went to enterprises and institutions, such as the National Supercomputer Changsha Center, Yuanda Group and Changsha Public Security Traffic Police Detachment, and then formed the urban development report of Changsha City in the eyes of young people, and submitted it to the Changsha General Planning Compilation Unit and the Municipal Planning Bureau.

Through the "Discovery of Star City", children's views and opinions are collected as widely as possible and integrated into the framework of master planning.

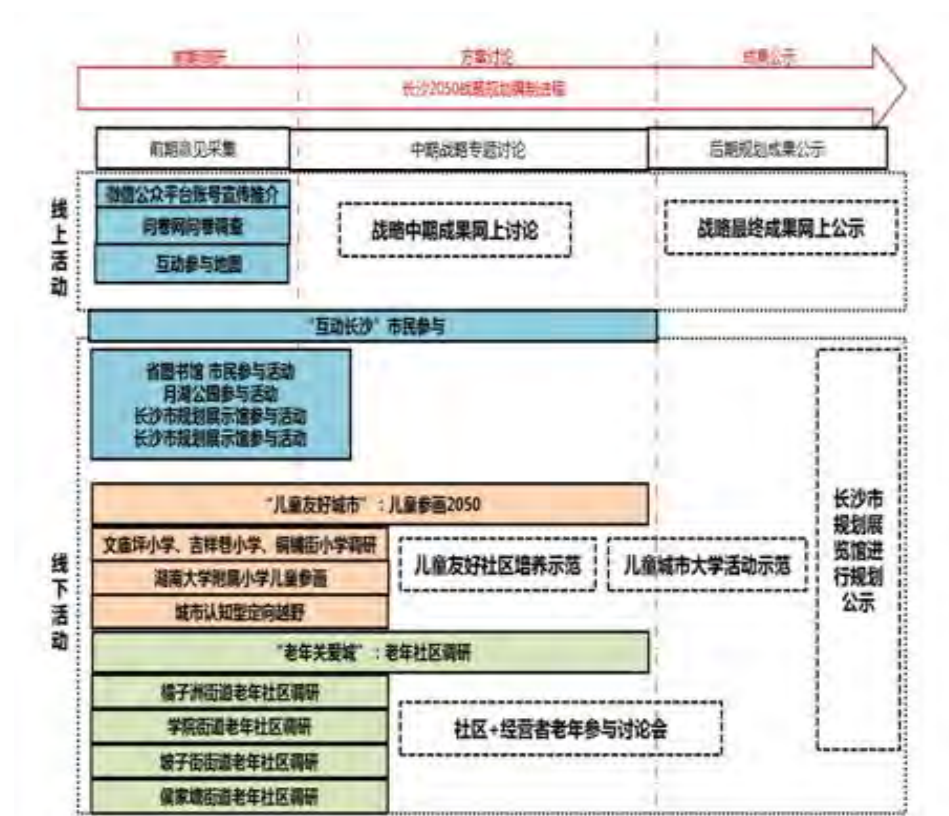

Figure 4 Framework for Public Participation in Strategic Plan

Figure 5 Children's Communication and Participation Activities at Macro-Level

3.2 Medium-Level

Medium-level content is the concretization of macro-level content, and the goal has spatial significance.

The overall path is to form a value consensus at the spatial level, pay attention to specific vulnerable groups in the process, advocate fairness and justice in resource allocation, and then implement spatial resource allocation based on the spatial value consensus, including facilities indicators, built environment and other levels.

Medium-level framework incorporates the communication and participation of children groups, which can effectively and accurately capture user needs, effectively reflect the problems to be solved in the

current situation of space, and jointly seek effective solutions that can be implemented. As seen in Figure 6.

Children's communication and participation can effectively improve the quality of planning content. For example, in 15-minute life circle planning, through communication and participation, can more accurately collect the status of life circle facilities configuration and use. If the indicators of educational facilities such as primary schools and kindergartens are reasonable, are there any problems in the actual use process?

For example, special planning for kindergartens and primary and secondary schools, through communication and participation, planners could further truly understand the real needs of kindergarten primary and secondary school settings from the perspective of children and family. How important is the school front space? What kind of space do parents and children need for parking, waiting, and etc.

Medium-level activities are carried out within the framework of master plan, generally in the form of "workshops", which follows the technical process of "organizing workshops - online and offline research - children and parent consultation - forming planning results".

For example, in the process of making special plans for kindergartens and primary and secondary schools, the research subjects of "Guidelines for Children Friendly Campus Planning" and "Symposium of Safe, Fair and Fun Children's Microspace" have been carried out jointly with professional institutions and universities.

At the same time, planning authorities continue to seek opportunities to communicate and cooperate with multi-sectoral institutions of education, health, transportation, primary and secondary schools, families and other subjects. Activities have been carried out such as "SNS Research of School Path", "Mind Mapping Workshop", "Little Planner Workshop" and "Children Friendly Microspace Symposium".

Relying on the Planning Information Center, the "SNS Survey of School path" builds the platform of "Changsha Mass Planning Map" and conducts research for school teachers, parents and students.

The respondents logged on to the "Mass Map" through Wechat, placed virtual map pins on the maps of home and school, and drew the location of high frequency stopover points in the routine routes and routes to and from school.

The information center collects the research data of Wechat in the background, forms an analysis report, submits it to designers, functional departments and social organizations, and forms the basis of bus route planning, slow-transportation system design, safety management regulations and other aspects.

"Mental Mapping Workshop" relies on cooperation with pilot primary schools. Let the teacher organize the planner to enter the campus classroom. Planners prepare the base map on paper and lead the children to draw the hand-drawn map of the school and the surrounding areas together.

First, planners introduced the content of the background map to the children, and let them establish a preliminary relationship between the drawings and the living space. Then ask the children to circle the most interesting places, the least liked places and the most feared places on the map. Legends are uniformed, black triangle represents safe and willing to stay area, red triangle represents dangerous zone.

The limited samples collected show that black is mostly distributed in the areas where crowds gather frequently in communities and parks, and red is mostly distributed in the intersection space of pedestrians and vehicles such as roadways and intersections.

"Little planner workshop" is in the design of "themed painting" and "wish note" session to encourage children to participate.

Cooperative Primary School integrates "theme painting" into the content of art lessons and encourages children to draw the ideal urban landscape. "Wish note" encourages children to write notes to express their views on the space of life, such as the most frightening things on the path to school, the best place to go, etc.

The school collects the results of painting and notes to planners, and planners analyze and sort out the results, and find that there is a strong correlation between aspirations, ideals and opinions. After that, the planner corresponds these related opinions to the specific space and gradually puts forward "problem list", "proposed solution" and "proposed project".

The "Children Friendly Microspace Symposium" includes a broader range of people, including children, relevant government authorities, industry representatives and Designer representatives. In children's group, the Hunan Organizing Committee of Xinhua Little Journalists organized more than 30 small journalists to attend the meeting.

During the symposium, videos of places commonly used by children are played. Children's delegations, industry delegations and Designers' delegations are invited to discuss the "friendliness" and "unfriendliness" of the space in videos. Consensus and suggestions on children's friendly space design are formed through presentations, debates and summaries. The activities result are compiled into the "Children Friendly Space Consensus" and "Symposium Pamphlet".

The results show that children's growth stage and physiological conditions are special, so that children's demands for space are also special, which cannot be fully covered by adult observation and logical judgment.

For example, some children respond that "the friendly part is that the community service center are painted in nice colors, but the natural light is insufficient, we should open more windows." It shows that some children's needs and perceptions of natural light are stronger than those of wall decoration. Some adult-led children's space renovation often overlooks this point.

Figure 6 Children's Communication and Participation Activities at Medium-Level

3.3 Micro-level

Based on the macro and meso-level, a multi-level value consensus and framework construction have been formed. The micro-level is more focused on the design and transformation of the micro-level

material space, as well as making corresponding decisions and implementing actions in the process of deliberation.

Activities carried out at this level include "10+2 pilot transformation of child-friendly campus", "child-friendly micro-space transformation contest" and "love & care zebra crossing". The micro-level communication and participation is more targeted. As a user group, children are directly involved in the whole process of reform design, project decision-making and post-implementation evaluation. As seen in Figure 7.

For example, "Children Friendly Microspace Rebuilding Competition". Organized by the competent planning department of the government, it is aimed at collecting safe, interesting and convenient public space schemes for children-friendly cities for planning and design groups and design colleges with independent legal persons in the city.

It advocates that urban planning and construction should be examined from a height of one meter, and that cities with temperature should be built, and that children's friendship should be realized for all. The team will choose the public space that children may use within one hectare of urban area to rebuild. After nearly a month's solicitation, 65 contest schemes were received. Many teams independently adopted the design method of children's communication and children's participation.

For example, the first prize team project "The design and transformation of children-friendly public space in Osmanthus Park", the team leader is also the initiator of "Mother and Female Planner Society". In the early stage of the formation of the design scheme, we carried out a preliminary base investigation on the combination of parent-child play links relying on the mother and female associations.

Through careful observation of parent-child activities and children's activities in the process of investigation, this paper puts forward a set of detailed problems and coping strategies in children's friendliness in parks. In the process of the formation of the program, we constantly communicate with the children group and get feedback from the children. Finally, a competition design scheme approved by both parents and children has been formed.

After the deadline for submission of the scheme, the Planning Bureau summarized all the contest schemes, determined 50 entries through the internal evaluation preliminary selection, and selected 20 entries into the expert evaluation process.

Through the expert review meeting, 4 out of 20 excellent works were selected to enter the public selection process. On the day of the mass election, four design teams of the selected works came on stage to present the contents of the works, and the "small voters" were on the spot to vote for each other. After that, nearly 300 primary and secondary school students went to the stage to vote in turn and evaluated the winning order of four works.

"Expert reviews mainly select works from technical and design perspectives, while mass reviews select works from aesthetic, experiential and child interest perspectives." Introduction by the person in charge of the competent department.

After the selection, the Planning Bureau reported the final results to the Changsha Municipal Committee and municipal government, and communicated with the district committees and the district governments. It tried to transform these good creative designs into practical results through micro-transformation, so that children's participation and decision-making could be changed visibly.

Actions at the micro level often do not involve the "big demolition and construction" of urban space, but through subtle transformation and fine management to achieve child-friendly at the spatial level.

The micro-specific changes in material space and management methods are the most direct part that can be touched and felt by families and children as users. This puts forward higher requirements for the fine governance and meticulous design.

Communication and participation at the micro level need the cooperation of two aspects. On the one hand, design professionals play an active role in the process of design, bringing children's communication and participation into the whole process of design; on the other hand, planning management departments need to establish a framework and platform to facilitate the common deliberation and decision-making of all subjects.

Figure 7 Children's Communication and Participation Activities at Micro-Level

4. Conclusion

In the context of China, government agencies, as the leading force of social development, play an important role in guiding urban development. In the process of building a child-friendly city, urban development is not only for the general public, but also for the growing children. Planning and design processes need to be highly communicative and participatory, so that citizens, as more dynamic subjects, can fully integrate into the urban development process.

On March 12 this year, director of Child Protection Department of UNICEF Office in China, and his delegation visited Changsha to explore the establishment of a child-friendly city in Changsha. The construction of Changsha children-friendly city is in progress.

The declaration of child-friendly cities is not an end, but a part of the development of people-oriented cities. The purpose is to make the society form more value consensus through communication,

participation and a series of urban events, so that the development of the city takes into account efficiency and fairness, and pays more attention to everyone real people.

Urban design for multilevel planning

A Multilevel Urban Landscape Measurement for Zoning Control – A case study of Gushan Kaohsiung in Taiwan

Jouhui Li¹, Han-Liang Lin²

¹ *Department of Urban Planning, National Cheng Kung University, p26074062@mail.ncku.edu.tw*

² *Department of Urban Planning, National Cheng Kung University, linx@mail.ncku.edu.tw*

Abstract: The zoning control in Taiwan is a legal regulation on land that emphasizes binding land use and density rather than landscape shaping of neighborhood, place, district etc. The current system of zoning and urban design guidelines in Taiwan lacks the perspective of urban landscape and results in high similarity of building and street-block's fabrics. The purpose of the study is to provide perspectives of urban landscape, architecture, street-network configuration for enhancing the ability of zoning control and urban design guidelines to describe and control urban form in Taiwan. This article firstly presents quantitative measurements to describe urban form and activities in the scales of streets, plots, blocks, and places. Three measurements are Choice measure of Space Syntax, building density measure by Spacemate, and land-use mixture level of Mixed-use Index (MXI). The data is obtained from the field survey into the detail of building form, uses of every floor, gross floor area of each land parcel of study area, Gushan District, Kaohsiung City, Taiwan. The result supports the information of building density, choice measure, land-use mixture levels in the scales of cadastral land parcels, blocks and places. The measurements and comprehensive classification from the overlay analysis help urban design guidelines of zoning control with the landscape perspective.

Keywords: Spacemate; Space Syntax; Zoning control; Urban Landscape

Introduction

Zoning control of urban planning is one of the most important legal tools that influence urban landscape. It is formulated in the regulations and urban planning regulatory documents under the relevant urban planning system in Taiwan. It mainly emphasizes binding land use and density instead of landscapes shaping in neighborhoods, places, and districts etc.

The current system of zoning and urban design guidelines in Taiwan lacks the perspective of urban landscape, and it results in high similarity of building and street-block's fabrics. Besides, it doesn't think about the relevance between urban physical environment elements (Lin, 2017 ; Ku , 2018). For example, in terms of land use intensity, Lu, Yueh-Tung (2017) proposed that the intensity of development for a zone decided by Taiwan's planning departments is mainly based on the width of the surrounding roads, no matter what kind of zones it is. When the surrounding roads are wider, the intensity of development is higher. And that means high floor area ratio and more allowable uses. It is a kind of planning thinking based on building management, and it does not take into account the spatial location, activity characteristics, configuration of infrastructures, development potential, and other physical environment elements of the area.

Urban design is also a part of zoning control in Taiwan, and it is implemented in urban renewal areas, land readjustment areas and specially designated urban design areas. However, most of Taiwan's urban design regulation documents are abstract concepts and lack the process of constructing a vision of the urban landscape. A urban design guideline is mostly presented in the form of text and partial drawings under a detail plan. The

urban design regulation lacks a more objective, direct and comprehensive way to be understand the landscape atmosphere of a neighborhood, place ,and district. That makes it difficult to grasp and discuss the overall spatial vision when planners draw up a detail plan and the principle of urban design in the local(Li, 2011). In addition, Taiwan's zoning control lacks the multi-scale discussion. Most of the regulations of zoning control, including the land use, allowable use, floor area ratio and building coverage ratio, are regulated in a block rather than a building lot. Taiwan's development mode is based on each cadastre, and a block usually has several cadastres in the most of regions excluding some big blocks in readjustment areas. That difference between the units in zoning control and development mode in Taiwan leads to the highly similar urban landscape in blocks.

Moreover, urban landscape includes the active landscape and the physical landscape. Hu and Yu (1984) proposed that from the point of view of *The Spirit of Place*, the active landscape is the soul of a place space, while the landscape of the physical environment is the body and skeleton that governs the soul. As a result, when we describe the urban landscape ,we need to analyze both physical landscape characteristics and the urban activities. And the compact development of the city makes vertical development a present and future trend, but the zoning and urban design regulation mainly discuss two-dimensional urban functions and tolerance without considering the impact of vertical space uses on urban landscapes.

Overall, the current system of zoning and urban design in Taiwan focuses on binding land use and building density. On the other hand, the system develops and analyzes the urban landscape respectively by independent fields of urban activities, buildings, landscapes, transportation, and so on(Yang, 2009). It is hard to shape the overall image of the city with the regulation and analysis of the separate elements. The purpose of the study is to provide perspectives of urban landscape, architecture, street-network configuration for enhancing the ability of zoning control and urban design guidelines to describe and control urban form in Taiwan. The study also shows the comprehensive results of overlapping the landscape characteristics in the scales of cadastral land parcels, street blocks and district areas, and the analysis can help urban design guidelines of zoning control with the landscape perspective.

Therefore, this study attempts to analyze the urban landscape of the Gushan District of Kaohsiung City in Taiwan from the perspective of quantitative urban landscape indicators at the cadastral land parcels, street, block, and place scales to understand the interaction between the elements of the urban physical environment and activities. Then it can help urban planners and designers grasp the overall living space of the city and understand the combinations of the elements of urban landscape at different scales. And it can be discussed what kind of landscape is shaped by the different levels of the diversity of vertical space activities.

Figure 1 Location map of the study area
(the left is the area of the Gushan District ; the right is the study area)

Studies and Perspectives of Shaping Built Environment

1. Built Environment Characteristics

The most extraordinary thing in the city is not that their morphological composition is so different, but that elements of their composition is so the same(Hillier, 1996). These elements that form the urban landscape are what this study would measure, analyze. The following discussion is about the elements of urban space and urban landscape in the views of urban morphology and new urbanism.

From the point of view of Conzenian School, one of the main schools of urban morphology, Conzen (1960) proposed the term *townscape* as the subject of his research, analyzing the three-dimensional form of urban space by three systematic components: town plan, building fabric and pattern of land and building use. *Townscape* is called as *landscape* now. The townscape comprises the three components that are defined below. Town plan is the most spatially ‘encompassing’ of the three components, and it has become an integrated method named as Town-plan analysis(Oliveira, Marat-Mendes *et al.*, 2018). Town-plan analysis investigates the patterns of streets, plots and buildings. *Building Fabric* can be analyzed and discussed by age, building type, construction materials, height and architectural style. *Land and Building Use* is generally considered to broadly recognizable categories such as residential, commercial, industrial, institutional, recreational activity or stand vacant. It shows the most small-scale spatial heterogeneity within the townscape. The three components of essential townscape elements form the physicality of the townscape. It is emphasized that the difference in stability or persistence between elements. As time go by, due to the difficulty in reorganizing and changing the ownership, the street is the most stable element, which refers to the urban street space between a block and a block. The second one is a plot. It can be divided into smaller plots by subdivision over time, or aggregated to form the same size as a block. Land use is the least persistent over time(Caniggia and Maffel 1984).

And the Italian architect Saverio Muratori (1963) proposed the *operational histories* as the basic theory of his architectural design to study the *types*, *organisms* and *urban fabric* for cities of different periods. Gianfranco Caniggia, who inherits the philosophy, continues Muratori's research with *typology* which takes the building

type as the root element of the urban form. And then the philosophy contribute to an important school in urban morphology which apply *typo-morphology* to study urban landscape, such as Giancarlo Cataldi, Gian Luigi Maffei, Maria Grazia Corsini, Paopo Maretto, and Giuseppe Strappa. Most of them continually use this concept to study urban patterns in Italy and other places(Moudon, 1997).

Combining the ideas of the main schools in urban morphology for elements of urban landscape, there are some important elements as follows. Conzenian school mainly uses streets, plots, architectural structures, and land use as the main elements of the study, and Muratorian school emphasizes the types of buildings in order to study the urban patterns in different periods.

In addition, under the wave of new urbanism and rationalism, more and more scholars discuss that the formation of urban space is closely related to the diversity of urban activities. They believe that the diversity of urban activities helps shaping good space of a city. Jane Jacobs (1961) proposed that urban streets and the surrounding land use constitute the urban space. The diversity of land use is important for the quality of urban public life and improving urban vitality, and it also stimulates the vertical development of the physical environment. Strict and single land use can make urban life disappear (Jacobs, 1993; Hoek, 2008). Following the context, the concept of compact city has also arisen. It has a great impact on urban design, emphasizing the importance of mixed use, high-density development, and development of mass transit to the city.

Integrating the aforementioned the ideas of urban morphology and new urbanism, this study considers that the elements of urban landscapes include streets, buildings, land uses.

2. Measuring Urban Forms

Besides, there are some researches about urban landscape by measuring some indexes. Space syntax , Spacemate and Mix-use Index are the most common methods to use in researches of urban landscape. Space syntax combines scientific analysis with people-oriented concepts, spatial analysis method based on spatial topology. Lots of researches use it to analyze the spatial configuration, connection of road network, space potential, etc. It is used to explain how human and architectural space are connected and the influence of space on social relationships and behaviors. It also classifies the space with spatial logic and establishes rules for the conversion of roads and passages into axes(Hillier and Hanson, 1984;Hillier, 1996).

Spacemate is a 3-dimensional spatial matrix The researches on Spacemate are mostly to discuss the different proportion of negative space and positive space. Spacemate focuses on various types of density on the urban block such as Floor Space Index (FSI), Ground Space Index (GSI), Open Space Ratio (OSR), and the number of floors (L). Spacematrix is a method created by the same people as spacemate. It has one more analysis than spacemate, and that is network density (N).

Burton (2002) believes that the mixed use of land should provide a variety of facilities and services in terms of urban functions. For urban residents, the mixed use of land should be a way of using land facilities that can accommodate both living and employment (Jacobs,1961).

Some studies discuss the combination of quantitative landscape analysis tools, such as Space Syntax, Spacematrix and Mixed-used Index (MXI) as a set of quantitative assessment tools for urban design (Ye and Van Nes, 2014). That has been applied to the assessment of urban design schemes in related research(Ye, Yeh *et al.*, 2016). There are not many studies about discussing urban form in Taiwan by using a method of combining spacemate(or spacematrix), space syntax, MXI. Lee (2016)uses Spacematrix and space syntax as two research methods to discuss urban forms in different periods. That replaces traditional research in urban morphology. With quantitative analysis methods, it can help planners to understand the urban form under the more diverse and faster development of cities now. The results of the above two case studies explain the relationship between

the socioeconomic status and urban form of a certain place. And the results help planners to observe the changes in urban density in different periods and learn the speed and shape of urban development at that time.

Methods

1. Conceptual Framework

Looking at the above studies about measuring urban forms, this study uses a conceptual framework as seen in Figure 2 that analyzes the urban landscape through quantifying the elements of *streets*, *buildings* and *land use*. This study would discuss about the individual results of three elements in the cadastral, streets and blocks scales for the study area. Then it shows the integrated results of the three elements and different forms of places.

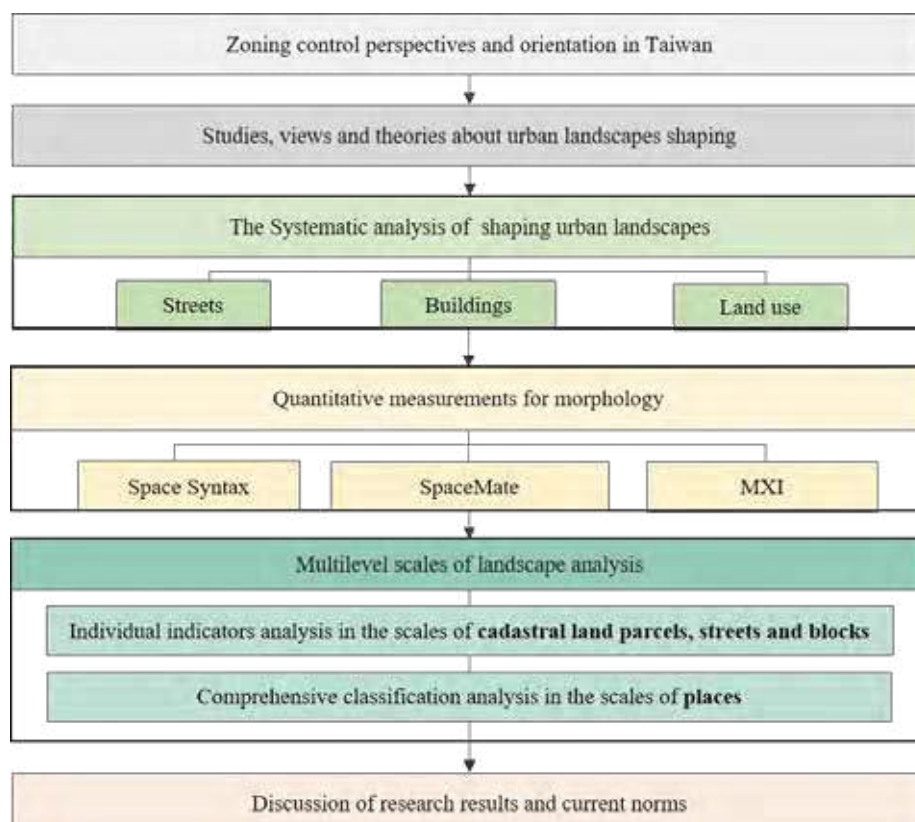

Figure 2 Conceptual Framework

2. Space Syntax

Space syntax is the architectural analysis theory developed by Professor Bill Hillier at University College London in the 1970s. Combining scientific analysis with people-oriented concepts, spatial analysis method based on spatial topology, he develops a set of indicators that can explain the spatial configuration. It is used to explain how human and architectural space are connected and the influence of space on social relationships and behaviors. It also classifies the space with spatial logic and establishes rules for the conversion of roads and passages into axes(Hillier and Hanson, 1984; Hillier, 1996).

Hanson (1999) discussed the forms of residential buildings in different eras with Space Syntax, and then Alasdair Turner assisted in the development of DepthMap software that integrates all the theories and techniques of spatial structure, increasing the production of visual graphics, speeding up the calculation, and automatically drawing Axis diagrams, etc. After the software emerged, Space Syntax is widely used in the researches in the architectural or urban scale(Huang, 2017), and become one of the main quantitative methods for studying Urban Morphology.

In this study, the choice which's indicators of Space Syntax focuses on measuring the extent of use of the road network. Hillier and Yang *et al.* (2012) pointed out that the *Integration* represents number of turns for selecting the another node as the destination from the starting point. *Choice* represents the number of times for the node being selected in all movements. These two indicators are both essential elements for measuring spatial mobility potential. Space Syntax can reproduce the moving characteristics of people in space. The areas where the integration or choice are relatively high are the locations that are easy to reach and pass in the space, but these values do not represent the actual distance (Hillier and Hanson, 1984).

The values of Integration and Choice are based on the least length, fewest turns, or the least angle respectively to calculate the shortest path. Choice is more suitable to reflect and predict human movement patterns (Peponis, 1989; Turner, 2016). In addition, Turner (2016) proposed that the angular segment analysis algorithm shows a better correlation with observed vehicular flow than the standard axial analysis and block-distance measures. Because this study will explore the relationship between land use patterns and street activities, it uses choice as a measurement for this area. Simply speaking, choice is to calculate the number of times for a node being selected, and therefore choice can also seen as the ability of a space to attract people. In general, most urban activities choose the shortest topological path, being calculated based on the total angles of the turn to reach the destination. This study uses the segment map which is converted from the road centerline of the local road network map of Gushan District, Kaohsiung City as seen in Figure 3 to calculate choice by angular segment analysis. The result of choice is recorded in the Cadastral map of the study area as seen in Figure 4 in the scales of cadastral land parcels.

Figure 3 Route Map of Gushan District, Kaohsiung City

Figure 4 Cadastral map of the study area

3. Spacemate

Spacemate is a quantitative method derived from the request of a typical post-war urban suburbanization in Amsterdam, the Netherlands. It assesses the density of buildings in the urban space. The density of buildings and building types are used to evaluate the urban environment during the process of planning and designing. They affect the various aspects of urban planning (Berghauser Pont and Haupt, 2005). Spacemate is a classification of regions of different urban forms by four quantitative indicators : Floor Space Index (FSI), Ground Space Index (GSI), Open Space Ratio (OSR), Layer (L). It is worth noting that the above indicators use the actual Floor area ratio and building coverage ratio rather than the ratios of legal regulations. The four indicators are placed in the 2-dimensional spatial matrix. According to the values of these four indicators, the study divides the matrix into sub-regions to represent different urban forms. That can help to understand how different combinations of four indicators of urban building density will form the urban form and create the classification of the built environment.

In this study, the data processing of Spacemate calculation is divided into the building density and building type. The building density of this study is adopted Floor Space Index (FSI), Ground Space Index (GSI), and the number of floors (L) as indicators for quantifying building density. The types of building are divided into three types: point type, strip type and block type. The buildings of point type are such as single-family building. The buildings of strip type are such as terraced houses. The buildings of block type are such as high-rising buildings. In addition, the analysis is divided into two scales: cadastral land parcels and blocks. The indicators and purposes are different between the analysis in two scales. The analysis in the scale of blocks is used to overlay the MXI and Space syntax results while the analysis in the scale of cadastral land parcels is used as a reference for observing detailed urban patterns.

Table 1 The data used for spacemate analysis

Analytical scale	index	Value/type	Data processing oriented
blocks	Floor Space Index (FSI)	FSI = floor area of all buildings in a block divided by the area of a block	Building density
	Ground Space Index (GSI)	GSI = The area of all buildings in a block divided by the area of the area of a block	Building density
cadastral land parcels	Average number of floors (L)	L = The total number of floors of all buildings in the a land parcel divided by the number of buildings in a land parcel	Building density
	building types	point type/strip type / block type	Building Type

4. Mixed-use Index (MXI)

The concept of compact city is on the rise with Mixed-use Index (MXI) to study the urban type, urban design, urban activities. Some studies use the elements such as work, residence, facilities as the main classification, and each plot can be comprehensively judged by the degree of mixed-use (Ye and Van Nes, 2014;Ye, Yeh *et al.*, 2016). The further analysis of the degree of urban spatial vitality, urban development, and urban types with the overlapping analysis of MXI and other morphological quantitative indicators. Besides, using Shannon's diversity index (SHDI) to determine land use diversity is a method of calculating the values of the entropy based on the concept of the biodiversity in ecology. The method has been used in land in recent years to judgments on the diversity of the land uses(Frank, Sallis *et al.*, 2010; Dhanani, Tarkhanyan *et al.*, 2017).

In order to judge the mixed use of urban land in Taiwan, this study is based on Taiwan's land use survey classification and actual observations. And the land uses is classified into residential, commercial, productive, infrastructure, and other use.

Table 2 The contrast between the classification of this study and Taiwan's land use survey classification

Classification of Land use in the study	Taiwan's land use survey classification
Residential (R)	Residential
Commercial (C)	Business
Productive (P)	Manufacturing, warehousing
Infrastructure (I)	Institutions, schools, health care, social welfare facilities, public facilities, environmental protection facilities, cultural facilities, park green space, leisure facilities, road related facilities
Other use(O)	Vacant land, religion, funeral, other construction land

This study explores the entropy of land uses. Zhang (2007), Frank and Pivo (1994), Cervero (2004), and Song and Knaap (2004) used the entropy of land uses for the studies of mixed land use. The more uniform and disordered the system is, the larger the representativeness is, and the larger the relative entropy is. The more systematic the system is distributed, the smaller the representativeness is. And the smaller the relative entropy value is. The significance of the entropy value on the block scale is the proportion of the land use in the blocks. The larger the entropy value, the more uniform the distribution of various land uses. The more mixed types, the more diverse urban activities occur in the spatial scale of the street. The entropy formula is below.

$$-\sum_{i=1}^n MXI_i * \ln MXI_i$$

Where i represents the different land use classifications of blocks

Calculate the entropy values of the various blocks and classify them through the number of times distribution maps through ArcGIS as a way to judge the degree of mixed use of the blocks.

Multilevel scales of landscape analysis and result

1. Analysis of urban landscape at the scale of streets with Space Syntax

The result in the block scale of Space syntax is as seen as Figure 5. The study calculates choice by the road network map via DepthmapX. In this study, the result of the road network is divided into eight categories according to the number of times as seen as Figure 6. The red lines in Figure 5 mean that there are highest values of choice on these roads such as Zhonghua 1st Road and Mingcheng Rd. The two roads are both the main road that can fast be passed through and get to other regions as seen as Figure 7 and 8.

Figure 5 Angular choice analyses of the study area with Space Syntax

Figure 6 The distribution map of the choice value of the road network

Figure 7 Zhonghua 1st Road

Figure 8 Mingcheng Rd

2. Pattern of urban landscape at the scale of cadastral land parcels

The landscape at the scale of cadastral land parcels can be discussed by the results of Space Syntax, spacemate, and MXI. First, the study uses the result at the scale of the streets of the Space Syntax as seen as Figure 5 and outputs the result that contains 8 levels of choice values to ArcGIS software to overlap with the Cadastral map. Number 0 is the lowest level of choice value while number 7 is the highest level of choice value. The choice values of the segments are as the basis for coloring each cadastral land parcel. The result of Space syntax at the scale of cadastral land parcels is as seen as Figure 9. The land parcels by the highest level of choice values are colored red. It's obvious that the large plot of land where Kaohsiung Museum of Fine Arts is located and the land parcels on both sides of Meishu East 2nd Rd and Mingcheng Rd are also red.

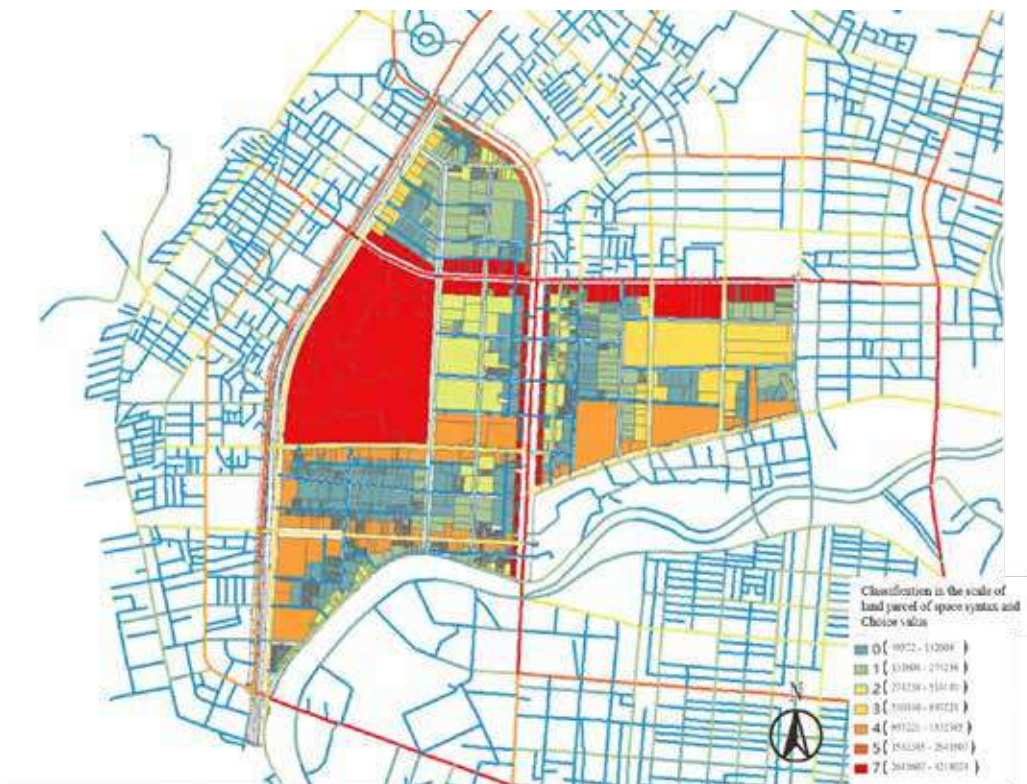

Figure 9 The result of Space Syntax by calculating choice values in the scale of cadastral land parcels

The analysis of building density uses the average number of floors of buildings and building types in each cadastral land parcel. The number of floors is divided into low level (0~2 floors), medium level (3~9 floors) and high-rise level(over10 floors), according to the common building forms in Taiwan.

There are three categories based on the building types. The building types are divided into point type, strip type and block type, as seen as Table 3. The buildings of point type are such as single-family building. The buildings of strip type are such as terraced houses. The buildings of block type are such as high-rising buildings. In this study, the value of the open space and vacant land is listed as another category. The Table 3 shows the building density categories which combine the 3 types of building forms and 3 categories of the average number of floors of buildings.

It can be seen as Figure 10 that the open space and vacant land are mainly distributed on the east side of the study area, and Aozihdi Forest Park and its surroundings form a distinct distribution of the building density as seen as Figure 11. The northwest side of the study area is dense, and the numbers of floors of buildings there are basically over 10 layers as seen as Figure 12. So the map shows a clear dark color for the high building density.

Table 3 Building Density Categories

Building Density Categories	Basis of Classification
High (3)	medium level with the strip type, medium level with the block type, high-rise level with the block type
Medium (2)	medium level with the point type, high-rise level with the point type, high-rise level with the strip type
Low (1)	low level with the point type, low level with strip type, low level with the block type
Vacant land and open space (0)	no buildings

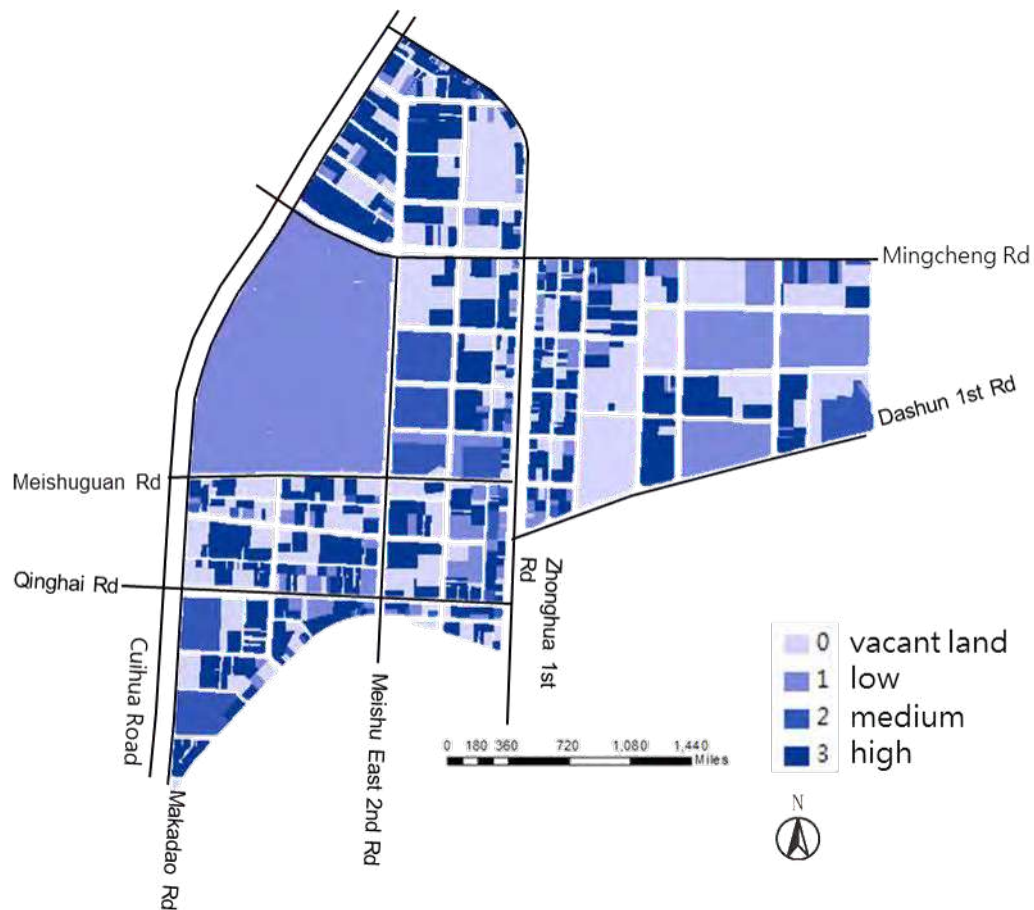

Figure 10 The distribution map of building density categories in the scale of cadastral land parcel

Figure 11 Aozihdi Forest Park and its surroundings

Figure 12 The northwest side of the study area

The result of MXI at the scale of blocks shows below. I (Infrastructure) is obviously the largest category of the main use category in the study area, such as the main park, art museum. The second is the R (residential) category because there are many residential buildings in the study area. Even if the first floor of some buildings is for commercial use, the main use is residential. P (productive) is concentrated in the southern half of the study area, and its use mainly in warehousing and manufacturing. O (other) is based on the use of open space or vacant land.

The distribution of mix-use levels in Figure 13 to 18 below can be seen that the proportion of different vertical uses in the scale of cadastral land parcels. Then the main land use of a single parcel is known. Most of the parcels beside the main roads and parks are mixed-use, and there are usually commercial or infrastructure use in the low floors in those parcels. According to the survey data of this study, the distribution of different land uses

on each floor can be colored on several maps. Those maps can become the reference of the database when planners reformulate or adjust the local plans for urban design and land use control in the future.

Figure 16 Distribution map of land use status on the 3rd floor

Figure 17 Distribution map of land use status on the 4th floor

Figure 18 Distribution map of land use status on the 4th floor above

3. Pattern of urban landscape at the scale of blocks

The landscape at the scale of blocks can be discussed by the results of Space Syntax, spacemate, and MXI. First, the study selects the highest choice value surrounding the blocks as the basis for coloring those blocks as seen as Figure 19. Compared with the actual local development situation, the result shows that the areas with the highest choice value are indeed highly developed than the other areas with a low level of choice. The road network of

the area with the lower value of choice mostly serves the neighborhoods and the communities. The blocks surrounding by the roads with the highest choice value are usually highly developed, while those with a lower value of choice are mostly surrounded by residential buildings.

Figure 19 The result of Space Syntax by calculating the value of choice at the scale of blocks

The results of Spacemate at the scale of blocks are based on the analysis of the indicators such as the average Floor Space Index(FSI) and Ground Space Index(GSI) of each block. The indicators are used to describe the different spatial density distribution of blocks. The FSI is the description of the influence of the elevation of blocks on the urban system, and the result is as seen as Figure 20. FSI corresponds to the actual floor area ratio, and the GSI corresponds to the actual building coverage ratio in the built environment. Through the scatter map and the actual observation of the types of the blocks, the study divides the street blocks into five types such as low building coverage ratio with low floor area ratio, medium building coverage ratio with low floor area ratio, medium building coverage ratio with medium floor area ratio, medium building coverage ratio with high floor area ratio, and high building coverage ratio with low floor area ratio.

Figure 20 Spacemate classification matrix in the scale of blocks

Through the above five classification results, the spatial distribution map is as seen as Figure 21. Within the scope of the study, the blocks beside the river which is located at the southernmost part of the study area are mostly with high building coverage areas. The followed areas are by the two sides of Zhonghua Road. The areas of low building coverage ratio with low floor area ratio are distributed around the Kaohsiung Museum of Fine Arts and near the Forest Park.

Figure 21 Spacemate classification map in the scale of blocks

On the other hand, the result of MXI in the scale of the blocks shows below. According to the distribution map of the entropy value of blocks as seen as Figure 22, the study divides blocks into five levels, which represent low mixed-use, medium-low mixed-use, and medium mixed-use, medium-high mixed-use, high mixed-use.

Through the above five levels, the spatial distribution map is as seen as Figure 23. The high mixed-use blocks are distributed in Zhonghua 1st Road and Mingcheng Road along the street segments. Due to some undeveloped areas and the existence of two large green open space in the study area such as Kaohsiung Museum of Fine Arts and Aozihdi Forest Park, the low mixed-use is obviously distributed around them.

Figure 22 The distribution map of the entropy value of blocks

Figure 23 The spatial distribution map of the entropy value of blocks

4. Comprehensive classification analysis in the scales of places

Combining the results of the previous individual indicators, this study combines those results to classify different types of places. Blocks and road networks are relatively difficult the landscape to adjust in a short-term,

so the study combines the results of the three quantitative methods at the scale of blocks to analyze the regional potential and mixed development by using the choice of the road network as main reference basis of classification.

The study area is firstly divided into high potential, medium potential, and low potential by choice values of the road network, then obtaining the final classification through combining the level of development and attributes of blocks. The classification as seen as Figure 24 includes six sorts like low-potential area, single-land-use development medium-potential area, and mixed-use development medium-potential area, low-development high-potential area, medium-development high-potential area, high-development high-potential area.

High-development high-potential areas are mostly with the high level of choice values, building density, and mixed-use. As seen as Figure 25, buildings in the area are mostly over 10 floors and have over one kind of land use excluding residential use. And they all face main roads in the study area. The FSI and GSI values of medium-development high-potential area are mostly higher than low-development high-potential area. As seen as Figure 26 and 27, the difference between the two areas is the actual building coverage ratio.

It's clear that there is the buildings in mixed-use development medium-potential areas are mostly three- or four-story terrace houses and have commercial or other uses on the ground floor while the buildings in single-land-use development medium-potential areas are mostly the same use on every floor, such as residential use, as seen as Figure 28 and 29.

Discussion and Conclusions

The purpose of the study is to provide perspectives of urban landscape, architecture, street-network configuration for enhancing the ability of zoning control and urban design guidelines to describe and control urban form in Taiwan. At the scale of the streets, the result of choice value of Space Syntax can be used to describe numbers of times that roads are passed through for. Most of lands by the roads that have high choice values are highly development, and the landscapes on them are tall buildings and commercial shops.

From the perspective of cadastral scale, it can be understood the relationship between land use of each cadastral land parcel and the neighboring road network in the analysis of the more detail scale. And that can help planners to formulate a more detailed plan on land. The results of Space Syntax, building density, the land use survey at the scale of cadastral land parcel, as seen as Figure 9, 10 and 13, show that the roads with the highest choice values are mostly the main roads in the study area. That means that the plots beside those roads have high development potential and more diversity of land use. Conversely, road segments with lower choice values are more suitable for residential use. In the future, it may be suggested that the lands by those roads can be planned for more suitable landscape.

The analysis of landscape at the cadastral scale can tell more precise details than the analysis of landscape at the scales of blocks and places. Compared with the true landscape, the result at the scale of blocks may be a little distorted due to the average values for all land parcels at the same block. However, it also needs to have an overview for the whole landscape when planners make the zoning control and urban design guidelines. Analysis at the scale of blocks is useful for zoning control and urban design guidelines in Taiwan now because the related

regulations of zoning control and urban design guidelines are mostly based on conditions of blocks and streets either than cadastral land parcels.

As mentioned in the previous literature, the urban landscape includes the active landscape and the physical landscape(Hu and Yu, 1984). The comprehensive classification analysis at the scales of places is important for completely grasping the landscape of each place in a region. For example, the low-development high-potential area mostly faces the main roads and filled with open spaces, one-story houses, or just undeveloped vacant lands. The area may be a kind of places that are flexible to adjust its zoning control and urban design guidelines to let it develop faster and suitable for its context. Through the comprehensive analysis at the perspectives at the scale of places, it can be known the shapes, the diversity of activities, and potential of the place.

There are two limitations to this study. One of the limitations encountered is that it's impossible to obtain the latest cadastral map, road network map, digital topographic map which are published in the same year. And the existing land use survey results record only the main use of land. There's no record of three-dimensional land use. Therefore, the three-dimensional pattern of urban activities cannot be accurately described. Another limitation occurs when performing the Spacemate analysis. The shape and area of buildings on the digital topographic map are not accurate due to the incomplete registration of construction or illegal construction. So this study takes lots of time to measure the actual area of buildings.

In addition, the study is based on the empirical investigation of in a readjustment area in Kaohsiung that revolves around the art museum, which is an important regional infrastructure. Relatively speaking, the result should be different from other urban areas, such as CBD and suburbs. Therefore, the future research classification criteria can be decided by the conditions of locations.

In the end, the development approach in Taiwan is based on cadastral land parcels. There are different architectural forms for each construction project of the different developers. Although this study has conducted three systems of landscape indicators such as *streets*, *buildings* and *land use* surveyed by the scales of cadastral land parcels and blocks, the final analysis results are based on the block scale. The analysis based on the block scale is carried out to understand the urban landscape of the places and blocks. The future study can use the construction project of the same developers as a unit to conduct quantitative landscape analysis, and compared with the project that belongs to other developers and locations. Then that can help to understand the urban landscape of different actual development bases more clearly and directly.

The Role of Climathon® in the challenge of Multilevel Ecological Planning

Viviana Lorenzo¹, Martina Massari²

1 University of Bologna, DA Department of Architecture, viviana.lorenzo2@unibo.it

2 University of Bologna, DA Department of Architecture, martina.massari4@unibo.it

Abstract: The paper explores through the lens of participatory processes the growing movement of Climathon®, understanding their potentiality in innovating urban planning. Climathon® are expressively collaborative design events, aimed at developing solutions to tackle climate change at the urban level. These events represent ‘safe arenas for experimentation’ where multiple levels of knowledge, institutions, resources and actors, are systematically involved in the development of ‘urban climate change experiments’ to increase resilience and foster the ecological transition of cities. Through documentary research and semi-structured interviews, the paper analyzes two European case studies, from the genesis of the challenge to the outcomes, to understand their degree of participation and inclusiveness, which forms of partnership and incentives make the ideas come into action, who are the actors and stakeholders involved, how charges and benefits are distributed, and how does Climathon® fit into local and regional planning. By reading the process beyond the products, the paper explores if these co-planning moments, if properly linked to the overall planning process, could represent a new form of ecological planning made of small incremental parts, foreseeing their replicability on regulation and decision-making practices.

Keywords: Climathon, urban resilience, co-planning, ecological planning

1. Introduction

To cope with the ongoing ecological and climate crisis (UN Environment, 2019; WWF, 2018; Steffen *et al.* 2018) and accelerate societal bottom-up contribution to the achievement of global Sustainable Development Goals, Agenda 2030 needs to refer strongly to local contexts and policies and to a multiplicity of small incremental actions. As confirmed in the European Urban Agenda (2016), in this context, urban institutions are invested of the crucial role to tackle global issues with new methods (Barresi and Pultrone, 2018) aimed at fostering urban resilience. Resilience, is here understood as a perspective and attitude (Gabellini 2018) that modifies and mobilizes planning practice, in reaction to shocks and stresses and in a process of continuous adaptation.

In this process, the contribution of participation as a foundation principle for “building resilience” (Stockholm Resilience Center, 2014; Biggs *et al.*, 2012; Folke *et al.* 2005) is widely recognized (De Boer, 2009), but the question raises difficulties because of the contrasting dimensions of scale (bigness vs. smallness), timing (long-term view vs. short term achievements) and different levels of knowledge (remote science vs. near knowledge and first hand experience) involved, between ecological and participatory action (Hester, 2007). The challenge for participation, according to

Hester (2007), is to put in place design capabilities that embrace the different social and ecological geometries, because ecological democracy “can shape distinctive and resilient cities” (*ibid.*). Against this background, we are witnessing increasingly frequent attempts by public administrations to involve systematically multiple levels of knowledge, institutions, resources and actors, in the development of the so-called ‘urban climate change experiments’ (Castán Broto and Bulkeley, 2013). It is the case of the participation of the Municipality of Bologna and of Lisbon to the organization of Climathon®2018, a 24-hour hackathon for climate action developed by EU EIT (European Institute of Innovation & Technology) Climate-KIC platform. Both the two European cities have undertaken a process of re-orientation of urban policies towards a resilience perspective, building space for experimentation on environmental issues. These experimentations are locally anchored but transversely oriented towards global issues, adapted to each referring context.

Through documentary research, semi-structured interviews and conversations with key players, the paper aim is to analyze, through the lens of participatory processes, the Climathon®2018 event in Lisbon and Bologna, analysing their differences and contact points, and its position with respect to the urban planning and the connection with the collaborative framework and the policies adopted by the cities, exploring their potential and limits in innovating urban planning. In order to draw this comparison, it seems necessary to start from the excursus of multilevel planning framework and the available tools that the cities are implementing to begin the transition towards resilience.

2. Bologna and Lisbon: multilevel planning frameworks for urban resilience

Bologna recent history shows the trajectory of the city’s urban planning and environmental policies intertwined with a holistic view of a collaborative city (Ostanel 2017; Massari 2018). This vision have seen a formal consolidation since 2014, with the approval of the “Regulation for collaboration between citizens and administration for the care and regeneration of urban common goods”. Thanks to the collaboration with Urban Center Bologna (now Fondazione per l’Innovazione Urbana - FIU), the city has been experimenting thematic neighbourhood laboratories (*Laboratori di Quartiere*), places of discussion on central issues for urban transformations (environment, reuse of buildings, welfare, urban regeneration) that have contributed to “increase the effectiveness of public action on the territory, promoting a broadened governance” (Evangelisti 2009). The thematic and place-based laboratories are the devices through which Bologna is currently aiming to connect the level of the practices with the macro policies. In 2006, the adherence to the Aalborg commitments for the implementation of Local Agenda 21, integrates collaborative policies in a framework of sustainable development. The opportunity to put the new approach into practice in the field of sustainable development and climate action was provided by the preparation of the SEAP - Sustainable Energy Action Plan (2012), a voluntary plan whose assumptions are based on collaboration between actors, local stakeholders and urban planning. Through the definition of a ‘protocol of understanding’ for the implementation between the Municipality and local stakeholders, the SEAP provides a formal commitment and sharing of objectives for the implementation and monitoring of actions. In 2015, Bologna adopted another voluntary tool, the BLUE AP - Local Climate Change Adaptation Plan (2016) that defines strategies and objectives starting from the current climate situation and prescribes the actions necessary to achieve them. The Adaptation Plan interacts with urban planning leading to the progressive adaptation of existing planning tools, in which it transfers certain environmental measures making them applicable. The two voluntary plans are necessarily based on collaboration

between actors, involving specific stakeholders on environmental issues, in project-oriented processes.

These devices were included in 2017 in the “Bologna Resilient City” vision, defined by the Deputy Mayor for Urban Planning and Environment Valentina Orioli as «primarily a slogan, within which we wanted to bring attention to the issues of mitigation and adaptation to climate change, and stress the need to tackle the issues in an increasingly coherent and structural urban planning framework». The effectiveness of the strategic choices of this vision passes through forms of democratic co-management (Allegretti and Herzberg 2004) of public resources, including the Participatory Budget (PB). PB in Bologna has been experimented since 2017. It entails the direct management of a portion of the municipal budget by the citizens, to finance a series of projects organized in different neighborhoods, previously defined through a path of co-planning on a territorial scale. The process foresees the direct selection of the co-designed proposals through an online voting, from which priority projects are elected to be realised in the following year. In 2017, the amount of one million euros of the municipal budget, has been set aside for 2018 and 2019 to be allocated to the Participatory Budget, while for 2020 the figure has been doubled. The process, saw more than 1,800 citizens participating in the co-planning events in both editions and respectively 14,584 and 16,348 people voting on-line for the realisation of the projects at neighbourhood level.

Lisbon was the the first capital in Europe to sign the New Covenant of Mayors for Climate and Energy in 2016 and will be Europe’s Green Capital in 2020. Many are the steps that the city took in the past decade to become a “Green, Smarter and Sustainable City” (Application Form for the European Green Capital Award 2020) encompassing: Lisbon’s SEAP (2010), managed together with Lisbon E-Nova, local energy agency that regularly organizes thematic public meeting with stakeholders (municipalities, NGOs, public entities, companies, students of higher education and professionals of the sectors under analysis); the Lisbon Strategic Charter (2010-2024) that starting from the city’s major challenges such as depopulation, vulnerability to natural events and loss of biodiversity, established three main objectives of ‘City regeneration’, ‘Climate change adaptation’ and ‘Connectivity of green spaces’; the Master Development Plan (PDM) 2010-2022 (2012), that was the result of a public discussion around 6 key sustainable questions and focuses on viable sustainability and local solutions, moving from zoning to block and street planning management; Lisbon 2020 Strategy (2013) that highlights the priority area of Low Carbon Lisbon; the Lisbon Climate Adaptation Plan (2017) that was the result of the national project ClimAdaPT-Local (2015-16), and the Lisbon Biodiversity Action Plan (2015-2020).

The development and implementation of these voluntary and mandatory planning tools is deeply rooted in the great efforts that the Municipality of Lisbon puts into participatory governance as a municipality’s strategy (Green Surge Project). This strategy has brought to an increase of the degree of participation in recent years, thank to several informative and participative actions connected to the *Lisboa Participa* platform portal (*Na Minha Rua Lx*, a portal and an app to signal necessity for intervention in green and public space; *LisBOAidea*; *Lisboa Debate*, a virtual and physical space of discussion around the city’s decisions; *Lisboa Aberta* for accessing the city’s open datasets) and that is well represented by the Participatory Budget (Orçamento Participativo Lx) process, one of the most successful experience of this kind in Europe so far. Started in 2008, Lisbon was the first European Capital to implement the Participatory Budget and today it represents a central forum for public decisions of the City of Lisbon. Lisbon’s PB chose from the first edition to recover a central aspect of

co-decision and not merely of consultation (Allegretti and Antunes, 2014) of the famous original model of Porto Alegre (Brasil). Through the online platform *Lisboa Participa* or during the several assemblies held each year, any citizen or non-governmental actor can present an idea for the city in the form of a project, that is then submitted to technical evaluation and public consultation, voting and implementation. The city commits 5% of the overall city's spending budget to the realization of the most voted ideas. During the 2017/2018 PB edition, the city invested 2.5M€ to realize 15 winning projects voted by more than 37.000 people, among 434 proposals adapted into 128 projects during the phase of technical analysis and public consultation.

This overview of urban planning and citizens participation in Lisbon and Bologna, shows a substantial consolidated tradition of the two Municipalities of using participatory approach in decision-making and collaborative action to face urban and environmental issues. Against this background, the contribution intends to analyze one of these actions, the Climathon® 2018 for each city, by reading the process from the genesis to the preliminary results achieved, to understand their degree of participation and inclusiveness, which forms of partnership and incentives make the ideas come into action, who are the actors and stakeholders involved, and how does Climathon® fit into local and regional planning, exploring their potential and limits in innovating urban planning. The analysis was carried out through semi-structured interviews with Valentina Orioli, Deputy Mayor for Urban Planning and Environment of the Municipality of Bologna, Valeria Barbi - Eu Projects, Climate change and Sustainability Coordinator for Bologna Foundation for Urban Innovation (FIU), and Francesco Rocca - Project Manager of Impact Hub Lisbon.

3. The performance of Climathon as safe arenas for urban climate experimentations

Climathon® is a global 24-hour marathon, aimed at finding solutions to climate change challenges through co-design¹, developed by EIT Climate-KIC, one of the eight Knowledge and Innovation Communities (KIC) created in 2010 by the European Institute of Innovation & Technology², to accelerate the transition to a zero-carbon economy. Climathon® is meant to be an action to catalyse innovation and encourage fresh new thinking from beyond the mainstream (*ibid.*) and a format that cities or other organizations interested can use, simply by applying to host the event on the official website. It originates from Hackathons, a popular format in technologists and makers communities during which a group of developers come together to challenge each other for a fixed amount of time, allowing participants to exercise creativity and to “maintain the code” (Taylor and Clarke, 2018), and in particular from Green Hackathons, a series of international coding events addressed to broaden participation and collaboration among ICT developers and sustainability practitioners and researchers (Zapico *et al.* 2013). Climathon® is nowadays taking the shape of global movement: it ranged from 20 cities involved in 2015 to 114 in 2018, 15 of which only in Italy.

As other Hackathons, Climathon® are moments of intensive and collocated collaboration (Trainer, Kalyanasundaram *et al.* 2016) during which participants with different backgrounds (ICT, environment, economics, technology, social etc.), skills (creatives, developers, designers, entrepreneurs, institutions' officers, technicians etc.) and levels of knowledge (university level

¹ According to the official event's website “Climathon empowers citizens, cities and local economies to come together to develop local solutions to climate challenges” (www.climathon.climate-kic.org).

² A body created by the European Union in 2008 to strengthen Europe's ability to innovate and formed by a community of more than a thousand partners among universities, research centers, companies including SMEs (www.eit.europa.eu).

students, researchers, decision makers, stakeholders, interested citizens, etc.) come together in a playful way to co-design solutions to tackle climate change in their city or region. The format proposed by Climate-KIC encompasses moments of information to introduce the topic, team building, brainstorming and networking among participants, experts and ad hoc stakeholders related to the challenge, training on business tools and presentation skills (business model canvas elements, pitching etc.), relax (yoga lessons, caffè and lunch break, movie screening, art performing etc.). The location also plays an important role, as often the event happens in appealing modern architectures (e.g. coworking places, innovation centers, museums) or original locations (renewed industrial buildings, former silos). As described by one of our respondents (Valeria Barbi - FIU) «Climathon® is not only a respectable scientific event, but is meant to be also a fun social event that focuses on the engagement on the climate change theme in an informal way». The working groups, often formed impromptu, challenge each other for a prize, which is typically the access to an incubation programme, following a strict timetable. This urgency, together with the competition, helps creativity to burst, while the awareness of the contemporary happening of the event in other cities of the world and the importance of the goal invests the participants of a sense of commitment and proud³.

Even if Climate-KIC does not refer openly to the word “participation” or “participatory design” in its Climathon® communication, many elements make these events a form of participatory activity (Taylor and Clarke, 2018). Namely, the tools employed such as team building activities, visioning or backcasting and design thinking methods, stakeholder needs’ analysis and dialogue, informal setting, action planning and prototyping, and other properties such as enlightening different kinds of knowledges, mutual understanding and learning, building trust and a sense of community (Lorenzo, 1998) which are typical outcomes of participatory processes.

In this respect, Climathon® represent ‘safe arenas’, where the participants, through co-design and ‘open innovation’ approach (Chesbrough *et al.* 2006) are allowed to ‘experiment’ and discuss openly, imagine and develop and eventually realize creative and innovative solutions, to global adaptation and mitigation issues. However since Climathon® deals with complex issues affecting a wide and diversified public, it seems necessary to critically understand the established format, the tools used (mainly business oriented) and the selected objectives, as well as its position with respect to other ongoing participatory and planning processes, to improve their degree of participation consistent with their mission and consequently their ability to increase the resilience of the urban contexts in which they are implemented. The following interviews, while outlining the Lisbon and Bologna case-studies, helped to analyze Climathon®.

4. The cases of Lisbon and Bologna

The 2018 edition of Climathon® took place on October 26th, with each participating city scheduling the 24 hours start and end, according to necessity. For the City of Bologna it was the third edition organized by FIU in partnership with Climate-KIC and the Municipality, and it took place in the headquarters of Urban Center Bologna (former name of FIU) at Sala Borsa. In the words of Valeria Barbi the decision to participate Climathon®, besides their membership in Climate-KIC, was due to «the theme [that] allowed us to combine not only an important and actual issue, such as sustainability

³ The analysis of the concrete development of Climathon® contained in this paragraph is based on the descriptions of Climathon programs around the world displayed in the official wes site, on the answers of our respondents and on the direct participation of one of the authors, namely Viviana Lorenzo, to the 2017 edition of Climathon® in Bologna.

and climate change» but also to practice «participatory processes, or citizen engagement, which are another of our core activities». FIU policy for participants' engagement in the event was, as Barbi reports, «to leave the participation very open, we have not identified specific targets (companies or subjects with particular preparation) as often happens in Hackathons addressed to a technological target. Neither we have set any age limits» and this paid in terms of diversity of participants, with a good gender balance.

The Municipality of Bologna was an active partner of all three editions, contributing to the event by setting the challenges and providing technical content. The challenges launched during the events, concerned issues related to the Adaptation Plan (Climathon®2016), the use of satellite data from the EU Copernicus project to increase urban resilience (Climathon®2017), while the third year (Climathon®2018) the challenge was linked to an ongoing municipal participatory process, the *Laboratorio Aria* (Air Laboratory), that provided the main theme, with the explicit request to participants to further develop the Aria App, one of the outcomes for the process, enriching it with more interactive features.

In the words of Barbi, the solutions that emerged encountered some obstacles, due to the lack of a clear follow-up path, in some cases left to the initiative of individual participants and partners, but also due to the peculiarity of the process and topics that characterize Climathon®. Barbi reports: «When we talk about Climathon®, and therefore of issues more closely related to climate change, it can be more difficult because the theme is very complex, more easily understandable for experts rather than citizen, who may have an awareness of the problem, but not related immediately to daily life [...] and because the projects that are born [in Climathon®] are also more difficult to achieve [e.g. sustainable mobility] and are complex to be managed immediately by a public administration». Despite the difficulties, in the words of the Deputy Mayor Orioli, the interest of the Bologna administration in taking part to the organization of Climathon® «lies in the exemplary value of this event and in its international resonance: the Climathon® allows to focus attention, for a limited amount of time but in a very intense way, because of its global repetition, on issues related to mitigation and adaptation to climate change and innovation through the use of technologies. It is therefore a 'climate experiment' very useful also for the dissemination of knowledge and awareness on environmental issues».

For Lisbon the decision to participate to Climathon® for the first time, came from a private initiative of a researcher. The Municipality of Lisbon was then involved through the intermediation of the local division of Climate-KIC. The team included Francesco Rocca of Impact HUB Lisbon, a local coworking space, part of a larger international network of spaces for entrepreneurs and social innovators. In the words of Rocca, the main reason to participate to Climathon®2018 for Impact Hub, was «a strong alignment between our strategy as agents for sustainability and supporters of environmental and social projects here in Lisbon and Portugal, and the goals of Climathon®, e.g. to work for solutions to local problems identified by the municipality».

The challenge for 2018 concerned smart management to reduce plastic and food waste in the city of Lisbon, and was proposed by the Municipality. Rocca reports: «The winners would have the possibility to develop their idea by being incubated here in Impact HUB for the following three

months and to do networking at the Web Summit⁴, and then the city intention was to implement the idea through the Orçamento Participativo. [...] In practice, this did not happen because the projects were all at the ideation stage and did not go ahead because of limited time or low interest from participants, mainly international students». This aspect is underlined also for Bologna by the Deputy Mayor Orioli, which confirms that «the resulting proposals are interesting for the Administration, but in general they need to be deepened to be effectively implemented in policies and public action», and that nevertheless «promoting a synergic approach between actions, processes and events around a key theme, allows to analyze the problems with greater depth, multiplying the points of view and the answers that the administration can put in place, also together with citizens, associations and other stakeholders».

In the opinion of Rocca, the success of the event relied in the flexible format provided by Climate-KIC and in the enabling space of ImpactHUB, and mostly in the relationships of value that arose among the participants and partners, rather than in the production of solutions: «One of the projects that won the membership here, C., became part of our team of coworkers [moreover] establishing relationships with the Çamara [...] and having the possibility to collaborate with them on other projects, was useful. But there was not much follow-up». One critical point for Rocca in Lisbon, was the substantially voluntary nature of the event and the lack of clear commitment and responsibilities of the partners in the follow-up phase, which prevented continuity in the process after the event.

Similarly, what Barbi in Bologna sees as positive in proposing this activity to citizens beyond the implications within the public administration or the realization of the project itself, is «to give life and organize events [...] that are however fundamental from an educational point of view, because they enter the negotiation process on climate change [for which] in the last United Nations conferences, there was a call to the direct participation of citizens, because it was understood that the real change comes from below. And in my opinion, events like the Climathon® are notably functional for this».

5. Conclusions

Based on the interviews and research carried out, the conclusions reflect the considerations of the authors and the necessarily specific visions of the interviewees. From the planning and policy excursus reported, it seems clear that both cities are putting in place many efforts to address in a more structured and normative framework, issues related to environment addressed through participatory approach, to tackle climate change at the urban level. While comprehensive environmental planning becomes necessary in face of urgent action to tackle climate change, Lisbon and Bologna have started to implement informal confrontation and collaboration moments that go further the typical forms of citizens' consultation on environment issues (e.g. Agenda21 forums), towards more active engagement forms such as public-private partnership (e.g. the SEAP protocol for both cities, *Bologna Città Resiliente* Call for proposals), co-management of common goods (e.g. Regulation for collaboration ... of urban common goods and Bilancio Partecipativo in Bologna, Orçamento Participativo in Lisbon), and thematic urban/neighborhood laboratories (Laboratori di Quartiere and Laboratorio Aria in Bologna) in settings that could be considered 'safe arenas' for developing 'urban climate change experiments'. In both the case-studies, the possible integration with successful

⁴ Winners of Lisbon Climathon® won also a ticket for Lisbon Web Summit 2018, the largest event in the world relating to the sector of new information technologies and the internet.

existing Participatory Budget processes, could represent an asset to legitimate and realize these ‘experiments’ while reinforcing the link with overall urban and environmental planning.

Climathon® can therefore embody ‘safe arenas for experimentation’ that embrace both local and global dimensions (Hester, 2007) and involve multiple levels (Walker *et al.* 2004) of knowledge, institutions, resources and actors, for which codified planning and design tools could result overstructured. As for the metaphor of “the path and the forest” (Lanzara, n.d., pag. 52-53) this sort of ‘project-action’, between design and prototyping, could mean for urban institutions to be able to experiment “local sequences that make sense” (Lanzara, *ibid.*) for complex problems, before proceeding further. This consideration resonates with the aptitude of ‘agile innovation’ (Wilson 2011) to create space for experimentation and learning, where top-down approaches are no longer sufficient to meet contemporary challenges, including rapid reactions to needs and fast assessment of the impact of the solutions, to avoid the risk of incurring into irreversible disruptions when moving in uncharted territories.

With regard to the inclusion and integration of Climathon® in local and regional planning, Ass. Orioli states that Climathon®, as a punctual ‘climatic experiment’ can be oriented to «offer specific answers to a theme or a problem treated through environmental and urban planning». However, because these process remains isolated from the very reasons of the planning overall process, only if effectively connected and integrated they can have a complementary role with respect to the actions implemented through planning. These considerations open the possibility for such interaction tools to represent portions of a new form of ecological planning made of small independent and incremental parts (Alexander, Ishikawa and Silverstein, 1975; Alexander, 2004), foreseeing their replicability on other regulatory planning procedures and decision-making processes.

2_Urban design for multilevel planning

Interdisciplinary Methodology for rethinking the urban layout via Multi Criteria analysis and indicator application

Abstract: Since the 1990s, due to exponential urbanization, the approach of urban and landscape architecture has been facing new challenges and as a result has been changing rapidly. The ever progressing development of contemporary metropolises has led to a rethinking of the structural composition of human settlements. These days the focus is no longer only on meeting the needs of expanding cities, but finding a suitable method to govern the transformations of existing structures. This paper aims to renew the idea of contemporary city spaces, considering also the requalification of existing urban infrastructure. The main focus of this research is a future configuration of urban infrastructure in twenty years from now, when urban mobility will have developed and be much more sustainable. For this purpose, a range of indicators will be used on the economic, functional and social level that can direct the regeneration of such structures by proposing them in a defined urban morphology and a – depending on those surroundings - flexible system of values. The intention of this interdisciplinary group's collaboration is to develop a multi-criteria method to support the design process of said urban layouts. Following the analysis of urban structure data collected from an area in question, qualitative and quantitative indicators will be identified through a series of strategies. They will then be subdivided by macro-topics such as environment, economy and social life, which serve as main “pillars” of the system. Due to its key role in urban infrastructure, the mobility macro topic intersects the other pillars and will be the main topic of our research. By way of balancing the four macro-topic variables, three different solutions will emerge: a solution of equilibrium, a naturalistic solution and a metabolic solution. A reality based exemplary case study will explain the process as a whole, emphasizing the individual steps.

Keywords: Methodology; analysis; indicators; green technologies;

1. Introduction

Contemporary cities are complex systems in which society, economy and environment interact. As an organism today's city responds to the unstable condition of its components and its process of 'metropolisation' is becoming unhealthy and unsustainable. Citizens are not identifying themselves anymore with the urban and natural spaces they live in. That process has disrupted the city as a place

of living, segmenting it with fences, restricting the collective life, further compromising the environmental balance, without offering suitable places to encourage the inclusion of citizens within their own city, moving towards an society of individuals, devoid of cultural identities and collective memories, moving towards a social implosion in the private space that discredits the urban public spaces. The paper aims to explore how urban planning and architecture can contribute to promote public health and well-being via the improvement of public and cultural urban spaces.

Barcelona has promoted an urban research about re-thinking the main infrastructure of the city: how will “the ring” of Barcelona present itself in twenty years? In October 2018, Barcelona CTPA, an association composed of professors and students from six Catalan architectural schools (ETSAB, ETSAV, La Salle, IAAC, ETSA Reus and the UIC Barcelona School of Architecture) and further international university institutes, organized a hackaton for rethinking the Barcelona city's ring highway as an urban public space. With the support of municipality and region of Barcelona, the event, “Des-cobrir Les Rondes”, has involved multidisciplinary skills, in a multi-level approach: citizens, urban planners, architects, designers, professors, students, administration etc.

2. Urban analysis

To achieve a working sustainable urban model, an integrated process has to be followed. New structural and operating references have to be devised to accompany the transformation of a complex urban system. Biosphere and ecosphere must coexist. The vision on future urban development combines environmental, socioeconomic and morphological points of view. In today's scientific debate Urban transformations replace Urban expansions (Campos Venuti and Oliva, 1993). The analytical approach of urbanism is becoming the re-thinking of pre-existence structures of cities: places of identity for citizens, places of environmental mitigation, places of social and economic development, a creation of new relations between all these different factors (Ricci, 2005).

2.1 “streets” as structural urban component

The case of “Des-cobrir Les Rondes” was an opportunity to develop this new kind of approach: the integration of the infrastructure's life cycle in the ever changing city life. With this initiative, Barcelona joins the reflection on the future of circular highways that have already been developed by other cities such as Paris and Amsterdam. The case of the Ronda in Barcelona, a fast-flowing road ring that is a nodal element of urban mobility, represented an opportunity for an in-depth reflection on integrated interventions. These roads are being questioned as they no longer solve the problem of traffic congestion due to their inability to absorb the traffic in the central area. They have been designed exclusively for private vehicles and not for public transport. In the modern and contemporary architectural debate, the role of the street has always been of a central importance. This is observed in the work of architects from Cerdà, Berlague, Garnier, Stubben, Unwin, Le Corbusier, Lynch, Kan up to Leon Krier, Bohigas and Koolas (Rykwert, 1982). This urban component is referring to different meanings. Streets can be the definition of margins or the places of connections. They can metaphorically represent the inner relationships of today's society or places of disconnection. Streets can be green boulevard as well as places of pollution, networks or borders. The street itself is a structural component of the city which deserves a discussion for its characteristic of being a place of oppositions.

3. The hackaton as a tool of urban exploration

At 37 km in length, the hackaton path of “Des-cobrir Les Rondes” was structured with various stops in different parts of the Barcelona highway, where the participants tried to reflect, discuss, and

propose new visions for this infrastructure. The ring highway crosses many districts of Barcelona of different social status, urban structure, and orography (the Catalan capital rises on a plain inserted between the Mediterranean Sea and a mountain system to the north and it is bordered by two rivers laterally). The different stages have seen the design intervention of different university teams in order to propose interventions for different parts.

The area of Les Roquetes, a suburb north-east of the Catalan city, offered the UIC team and the researchers of Sapienza University of Rome a field of reflection on the requalification of the contextual infrastructure. The selected area has been chosen to focus the analysis on a particular road Ring section of Barcelona: its intersection with one of the main roads, Carrer Julia, which divides the area in four different neighborhoods. The urban analysis of the ring's path was articulated in three different phases. The first step was to recognize the different functions in the area, services and residential tissues, and above all the abandoned and interstitial area, taking care of morphological urban dimension. The second step was to analyze the connection between the most relevant services and public areas, such as the neighborhood market or the public green areas. To understand their area of influence two circles were drawn, according to the historical dimensions of the Cerda's urban square matrix, 100 meters from one another, highlighting the socio-economic dimension. The mobility system was analyzed along with this phase identifying Passeig Valldaura as a structural element of the area: being parallel to the Ring, it intersects Carrer Julia and the main road Avingua Meridiana. The third step was the analysis of the environmental system: the orography, the hydrography, the agricultural surroundings areas as well as public and private green areas.

The urban analysis aims at building quality and quantity assessments in order to evaluate the students' projects according to specific and scientific indicators. From the student's researches two main approaches have been outlined: the metabolistic and naturalistic one.

4. Metabolistic Approach

The Hackaton Des-cobrir Les Rondes aims to re-think the ring infrastructure as a driver of sustainable urban development to enhance social, economic and ecological resources. The purpose of the future vision about "Las Rondas" is to get to the concept of sustainability as defined in the Burtland report (WCDE, 1987) "A sustainable development meets the needs of the present generations without compromising the possibility to satisfy the futures one's". The Metabolist method reads the city as a natural and complex organism. The critical development which affects the environmental ecosystem has to be stopped. The Urban Metabolism has to solve "un-sustainable settlement processes" (Tiezzi et al., 2007). Contemporary cities represent a fundamental change in human settlement patterns and entail a dramatic transformation of the physical environment (Hosier, 1993). Cities and metropolitan areas, occupying the 2% of world's land surface, use over three-quarters of world's resources and discharge similar amounts of wastes to the environment (Baccini, 1997; Barles, 2010; Giradet, 1996).

The hypertrophy (Carta, 2015) of urban development clashes today with an economic and environmental crisis that requires a development of new paradigms. Reading the city as a living organism is the base of urban metabolism proposes, a complex system within which ecosphere and biosphere interact. "Metabolism", according to its medical meaning, is the phenomena of chemical transformations that take place in cells of eukaryotic and prokaryotic organisms in a coordinated and finalized way, to which many enzymes and intracellular multi-enzymatic systems cooperate. Metabolism's main functions are: to obtain chemical energy from the degradation of nutrients rich in energy, from the environment or from solar energy; to convert nutrient molecules into the basic precursors of cellular macromolecules; to form proteins, nucleic acids, lipids, polysaccharides and other substances using these basic precursors; to form and to degrade biomolecules necessary for specialized cell functions (Treccani). The abstraction from the medical comprehension of the phenomenon applied to the urban and metropolitan transformations identifies proactive strategies as main functions: to produce the energy and materials necessary for the demand of urban life through the use of biotic and abiotic resources (Longhi, 2016) existing within territorial system; to regenerate

through the conversion of places and infrastructures into areas of production of goods and services designed to ensure the biodiversity of the urban system; to recycle "technical nutrients" by inserting them into the urban production cycle since the waste by disposal or by use; to reduce waste elements, polluting gas emissions, introducing the concept of circular economy and short supply chain, thanks to the position and strategic distribution of different urban functions.

A system afflicted by a pathology of urban blight, strictly connected to the chronic demographic increase, is a system destined to extinction. The responsibility to define a strategic vision, able to use resources to produce the energy needed to generate and regenerate itself, is the new paradigm that we are now required to follow. The "slow" metabolism of contemporary cities, capable of assimilating and producing energy through a huge environmental impact, is ending resources without providing for their renewal: "every aspect of urban life weighs heavily on the planet's overall biological balance" (Ricci, 2013). The new metabolic paradigm proposes proactive policies to generate new opportunities related to the quality of urban life. The main actions are therefore that of reducing the environmental impact, the production of green energy, the production and maintenance of biodiversity through the increase of services, products, protected areas, urban food production. The purpose of urban metabolism is to anticipate unwanted events based on present signals, analysing the directions of the various flows of energy, water, nutrients, materials, waste, and quantifies the entrances, exits and parts stored in urban regions. In the early 1970s, the analysis of material flows through urban ecosystems was also promoted by UNESCO, with a program (Man and Biosphere, MAB) aimed at studying natural and social processes in an integrated way (Unesco, 2010). A very well-known index is the ecological footprint (Wackernagel and Rees, 1996) which measures environmental pressures determined by anthropic systems, expressing the "quantity of nature" necessary to support the metabolism of people, cities, regions, nations or anthropogenic systems (Cagnoli, 2017).

5. Naturalistic approach

The features assumed by the design of green spaces in the contemporary city, are the architectural-cultural products of past eras, where modernity and post-modernity have left strong residuals in a framework of unconnected and divergent approaches. Nowadays, with the affirmation of the new values of green in ecological culture, it is necessary to shift the focus of attention from the individuality of the 'interventions' of environmental requalification, to the overall picture of the different natural systems as a synthesis of physical and formal representation of places (WU, 2014). Linking green infrastructures to the other infrastructures of public space (blue and grey), means that they can either overlap, generating tree-lined avenues or green castings, or determine nodes of connection among different public spaces (for example a complementing pattern of green, blue and grey textures in public space).

The main goal is to develop a "green system" that structures the landscape from morphological and functional point of view. To realize such green system as a natural network, it is fundamental "to guarantee the coherence of the regional open space system" for each element of the system (green plots, green belt, rural crown, green band), some intervention strategies (Sdrif, 2013). The common denominator of all strategies, is constituted by the reticular ridges of the urban infrastructures (the threads that make up the great rope of infrastructures). The infrastructural lines can become, in fact, the great public spaces of the future as dynamic elements, fundamental for the city, whose ductility is necessary to the urban system. With this in mind, a new perspective on infrastructures is fundamental; current uses give them an important value: they are accumulation basins where human traces and collective memories are stratified over time; it is the city's facilities that need to be integrated into a new urban concept, rather than being judged to be inadequate to the city. Hence the idea of exploiting the green (naturalistic system), blue (water system) and grey (street system) infrastructures as tools at the basis of green planning. Compared to traditional infrastructures (grey infrastructures) conceived with a single purpose, green infrastructures have many advantages (Yeang, 2009). The use of green infrastructure can provide social, economic and environmental benefits, such as the absorption of excess water caused by heavy rains and the reduction of floods, the mitigation of the phenomenon of

heat islands in urban areas, energy savings, the creation of spaces and habitats for wild flora and fauna, and the spread of places for outdoor relaxation with consequent improvement of health and well-being of citizens (Suškevičs *et al.*, 2017).

6. Matrix creation process

This paper highlights the naturalistic approach in line with Landscape's values to guide the urban transformations.

a. Pillars

The latest city planning approaches to urban analysis recognizes three main pillars for identify the opportunities and vulnerabilities of urban areas. This is according to the sustainable development goals announced by the Urban Agenda of the European Commission (Urban Agenda, 2016): Environmental System, Social System and Economic System. Far off from a standard urban analysis, the methodological approach puts into effect a complex procedure of investigation, with the purpose of formulating a general rule that could be valid for different cases. The method follows four different steps: the first step is to observe each individual system using quantity data on the existing conditions; the second is creating different assessment ranks belonging to each type of pillar; the third is to choose two evaluation assessments suitable and common to all the three main pillars; the final step defines these steps, rules and guidelines regarding the "where" and "how" to develop urban projects must be established. This translates into a set of coherent operations aimed at enhancing the green spaces and together with the redevelopment of the landscape, promote the public space (streets, squares, parks, gardens), improve circulation and accessibility between newer neighbourhoods, and ensure the continuity of agricultural land (Spens, 2003).

b. Indicators

In order to create the "Naturalista" matrix, it must be made clear witch aspects of nature the term is actually referring to in this context. Due to centuries of cultivation and exploitation, there is almost no area in Europe untouched by civilization (Assunto, 1994) and more importantly the fact that the site in question is an important inner-city area, the possibility of "returning" to nature, even a renaturation (Clemént, 1991) - in the sense of it being recaptured by nature - is out of the question. However, answering this question is of major importance for the function of the developed matrix.

The analysis-based objectives have to be described precisely, in order to have a clear mapping of the resulting strategic "tools", which might comprise very physical i.e. technological solutions as well as more process oriented or social courses of action. Wherever possible, the question or task itself should be formulated independently of already known solution strategies, which is one reason that makes interdisciplinary working groups so valuable (Lehmann, 2010). The possibility of seeing the same objective from different professional perspectives qualifies the immediate search for a solution. For a collection of possible strategies in the field of "nature" that can respond to corresponding indicators from the analyses, first of all the above-mentioned question of the kind of nature and thus also its significance for the future development of the city has to be discussed. This represents one of differences of the method presented to others already in use: Having determined – via the urban analysis - the need for green space and the rededication of an available urban space as a possibility, the solution found by the different professionals can be very divers and give way to a innovative creation influenced by all participants. As an answer, there might not be only the obvious solution of a city park as a recreational area. In thinking that way it might be possible to create (even possibly required) free green space, but this could at the same time enhance the contrast between city and nature even more. Instead, the implementation of nature and nature-based technologies as part of the citizens daily life could be further developed, maybe even including elements previously unknown or perceived as separate from human life (Austin, 2014). This way, the permanent inclusion of a concept in the development of a society is ensured.

The special element in this case is the combination of the search for a conversion of an existing structure, which in its present use is considered obsolete in the future, into an element or a symbol of something inherent to humans - nature. Another noteworthy fact regarding this aspect is that natural elements have always been a desirable part of the environment of human dwellings (Benton-Short and Short, 2008).

Building physics or ecological aspects such as the improvement of the urban climate through regulation of temperature, retention of rainwater, reduction of noise and particulate matter pollution, or also a possible improvement of the carbon dioxide balance, have already been researched a lot and are still topic of ongoing studies. According to the study “Cities alive: Green building envelope” - performed by Arup in 2016 - covering many of these technical issues (Pauli and Scheuermann, 2013), the “most important” finding is that “green infrastructure, irrespective of where it occurs or how much space it covers, always elicits positive responses from people, because it is an aesthetic asset and an asset perceived as an improvement of the quality of life” (Pauli and Scheuermann, 2017).

c. Assembling the Matrix

Once the importance of integration has been recognized as such, there are a number of ways to bring about the presence of green or nature in the city. In this example, various variants of public and private green spaces, environmental or urban climate influencing elements were included as well as didactic, productive or transport related aspects. Depending on the desired scale or level of detail in planning, these strategies can then be further developed with the help of qualitative as well as quantitative assessment and with the same principle of sequential interdisciplinary analysis. When the strategies found are confronted with actual technologies, the options on new combinations grow, enabling innovation and thinking outside known paths. If desired and for a further deepening of the topic, an optimized and especially adapted use of technological possibilities for the site can be found such as an application of the various variants of roof or facade greenery, rain-, gray- or blackwater management, the countless and currently daily evolving possibilities of urban farming and distribution, or novel modes of mobility solutions, to name just a few.

At the building scale, the “Naturalista” matrix proposes passive bioclimatic solutions for the technological environmental requalification of the existing built heritage: the building system is in harmony with the surrounding environment and tends to use the natural thermodynamic and fluid-dynamic flows; it uses the material and immaterial physical forces coming and available from the micro-environment (Tucci, 2006): sun, water, wind.

Among the main solutions that can be considered implementable in the field of energy consumption of the building: the naturally ventilated building envelope, the buffer zone, the solar greenhouse, the bioclimatic hall, the insulating or capturing glasses, green roofs, green facades; in the field of indoor air quality: natural ventilation system, ventilation chimney, indoor greenery; in the field of total water consumption mainly the collecting rainwater system. The proposed solutions are based on analysis related to building orientation / lightning conditions, climate zones, solar / thermal analysis and technological analysis.

7. Data Visualization and information design

Today society, our countries, our cities even our houses can be considered as a data factory that produces a huge pool of information: the ubiquitous information society (Hanna and Peter, 2011). The necessity to show an information, a piece of life, and idea, could be traced back to the petroglyphs during the paleolithic era – this attitude is essential to human behavior. Books, monitors, computers, smartphones and so forth are just the natural evolution of this aim to communicate. In ancient times, information was circumscribed to “finished artefact” – such as books, while today’s interface is often a sort of screen. Every information must be clearly communicated to be useful, using the right tools and visual language. Data design and information design are the key to understand and share a

complex structure of information to the widest possible audience. Understanding the importance of the research developed and described in the previous paragraphs, the data visualization has to be considered from an aesthetic point of view, but most importantly as key to explain archive the research goals.

The entire research process of “Des-cobrir Les Rondes” has been visualized by three different typologies of graphic panels, each of them characterized by specific communication goals.

The 3 macro categories of panels are:

the Methodological Panels

the Approach Panels

the Scenario Panels

Methodological Panels

This category is composed of 3 main panels, each of them focused on a point of view of the main analysis (social life, environmental, economy). The aim of these visualizations is to explain and clarify the logic workflow of the entire research via a structure of the information that allows everybody to understand the methodology of the process.

The composition layout includes 4 banners of contents (named from A to D) linked to each other according to the logic of consequentiality and sense of reading from top to down.

A Banner defines - by tables and graphics – the amount of data, taken from different sources, used to understand the phenomena of the examined topic. It is helpful to take a general overview of the problems emerging from the Rondas.

Fig. 1. A BANNER – analysis of the actual situation

B Banner (see fig. 2), starting from the analyzed data of the context, it shows the qualitative indicators and the relationship with each other, considering the topic analyzed. The graphic pattern use is a flow diagram scheme.

Fig. 2. B BANNER – Indicators

C Banner (see fig. 3) is the section of the panel used to describe the process implementation matrix, by a horizontal graphic development in order to clearly identify the "before and after" comparison defining what are the key points for a reasonable strategy. The different indicators are visualized by a gradient of black shapes.

Fig. 3. C BANNER – Matrix

D Banner (see fig. 4) represents a visual concept scenario using the graphic technique of the axonometric view - admittedly abstract and non-figurative. The three incremental strategy visions displayed are the result of the intersection of the data taken from the analysis and through the application of the matrix. These scenarios represent the extreme perspectives of the topic.

Fig. 4. D BANNER – Scenarios

The Approach Panels

The second category of panels represent two of the possible approach strategies: metabolic and naturalistic. These data is graphically designed using a flow grid – as seen in the methodological panel – banner B.

The structure allows the identification of the difference between the two strategies and explains the approach and implementation in order to achieve the goals.

Scenarios Panels

The last panel (see fig. 5), is the final combination of the research process carried out by the methodological panels. In this case, the abstract scenarios are upgraded by the "real" data, balancing the topics: environmental, social life, economy.

From an aesthetic point of view, the panel presents three horizontal banners of equal size and kind of contents - described as E banner indistinctly - tracing its origin from the visual style of elaboration of Banner D into the methodological panel, and aims to represent a complete reading of the phenomenon analyzed in the research.

Fig. 5. E BANNER – Example of one scenario

Each E Banner describes how – by a non-figurative abstraction point of view – a city could change if the applied strategy focuses more on increasing public and social activities, rather than environmental issues. The data shown remains easily understandable thanks to the use of the same visual language.

Conclusions

The working-method developed was successfully applied in this and should be usable in many other areas due to its generic basis. In any subject of application, an objective analysis of the circumstances is essential, especially for the development of innovative solutions in areas with a large number of influencing factors. The advantage of a interdisciplinary group is evident as soon as the research's results demonstrate new combinations of sustainable visions to remodel urban components. Different

solutions meet the various necessities of the everlasting society's metamorphosis, in a necessary dialog with the hosting landscape. A "strategically obsolete" infrastructure, like the "ring" in this example, can be actively reintegrated into the city body, creating a newly defined urban space. Different scenarios, elaborated through the multi-criteria analysis and qualitative and quantitative indicators, are proof of the potential of this type of component in a strategic urban development. The multidisciplinary team was the cornerstone to create such a number of different solutions.

Collaborative processes and spatial planning: the national spatial planning policy in Portugal

Abstract: As Patsy Healey (1997) argues, the growing interest in public participation and the rise in more collaborative governance processes in spatial planning since the 1960s is evidence of the efforts made to overcome the weakness of the representative model, as well as foster communication among multiple stakeholders, so as to respond to the growing expectations and needs of citizens. Faced with less direct intervention in society and the economy by the State, building a more participatory democracy that coexists and enriches representative democracy is crucial. In Portugal, public planning policies are relatively recent. The guidelines and strategic options for territorial development are outlined in the National Programme for Spatial Planning Policies (PNPOT). Recently (2017-2018), the PNPOT was reformulated, with the intention of defining the spatial planning and development strategy and designing the new action programme for Horizon 2030. The proposal was open to a period of public discussion and was then submitted to the Portuguese parliament for possible approval. This study intends to explain the levels of governance and collaboration in the development of this national programme.

Keywords: collaborative planning; spatial planning; public policies; PNPOT

Introduction

The political and academic agenda has increasingly been focusing on and intensifying the debate around public participation and the growing number of collaborative government processes in spatial planning policies and practices. However, this debate is not new. In the 1960s, given the acknowledgement of some shortcomings in the representative model and a very hierarchical, vertical and centred State, the importance of engaging citizens in planning and decision-making processes was reiterated to enable the design of more inclusive policies that met the needs and expectations of the population (Davidoff, 1965; Healey, 1997). But little changed at the end of the 20th century. In the 1990s, government decision-making continued to be hierarchical and centralised, and discussions on the State's modus operandi came into the spotlight. A new form of a public administration was needed, driven by governance policies, which help shape the State's new role and new conception of intervention, encouraging more flexible and open procedures (via different forms of public

participation, involving a network of different public and private players). This led to a paradigm shift, from government to governance (Ferrão, Tulumello, & Bina, 2015; Stoker, 1998).

Collaborative and governance processes became key to designing public spatial planning policies (Ferrão, 2014). By engaging different stakeholders (citizens, policy makers, technical experts and other stakeholders) one fosters knowledge sharing, social learning and civic and institutional empowerment. The inclusion of citizens in the process can certainly produce better outcomes than the traditional processes that are usually envisaged in legislation. Thus, today, to enhance the democratic inclusion of citizens in more collaborative and smarter governance processes, there is greater acknowledgement of the importance of public debate and the promotion of citizenship (Allmendinger, 2017).

In Portugal, the spatial planning policy is relatively new, which explains the lack of an adequately widespread and autonomous academic and business community (Ferrão, 2014; Marques, Veneza, & Maia, 2019). It is a country where Community policies have a considerable influence given the scale of public investment involved, leading to significant public exposure and development thereof. Spatial planning is a national policy and, therefore, is attached less importance in the political debate as it is only funded indirectly by Community policies. Moreover, traditional planning values are still deeply ingrained in civic culture when it comes to territory, due to the country's recent and rapid urbanization (Marques et al., 2019).

The guidelines and strategic spatial development options in Portugal are outlined in the National Spatial Planning Policy Programme (PNPOT). This instrument is key for designing building the pathways that connect the various levels of spatial planning, as it must ensure consistency in sectoral policy interventions in the territory and define the general guidelines for the other land management instruments (LMI). In drafting these instruments, participation and collaboration between the various stakeholders must be envisaged and taken into account at the outset, from forming the task force to discussing the draft bill in the National Assembly.

In August 2016, Portugal initiated the amendment of the PNPOT, which was approved in 2007. This paper is a brief discussion of the key points in the participatory and collaborative processes carried out. To this end, twenty interviews were conducted with key players in the process to critically reflect the way in which the work was organised. Participation highlights and the dynamics of collaboration are also included. PNPOT 2007 assessment documents and those drafted during the amendment process thereof were analysed (minutes of meetings and public debate sessions, public discussion weighting documents and various technical documents), as were video recordings of public hearings held by the Assembly of the Republic at different points during the drafting process.

1. Conceptual framework

1.1. Participatory process in spatial planning

Since the 1960s, there has been greater interest in public participation and an increase in the number of more collaborative governance processes for spatial planning. It is an attempt to make up for some of the shortcomings in the representative model and to address the need to connect the multiple

stakeholders in order to meet the growing needs and expectations of the citizens (Davidoff, 1965; Healey, 1997).

The State's decreased direct role in society and in the economy, and the historical shortcomings of an overly hierarchical, vertical and centralised political power, reflect the need for "smarter planning" in favour of a more participatory and collaborative democracy that enriches representative democracy. This means shifting from standard decisions to designing more efficient and effective public policies, based on principles of more centralised, responsible and transparent public and land management, where "citizens play an active role in the decision-making process for public policies" (Davidoff, 1965).

There is greater acknowledgement of the importance of public debate and the promotion of new civic processes to enhance democratic inclusion (Allmendinger, 2017). A democracy that should be better informed and enlightened, enabling each citizen to be heard and well informed, as only thus will they be able to participate and understand the decisions to be taken, having the power to act and be an effective member of society (Arnstein, 1969, 1975; Davidoff, 1965; Verba, 1967).

In terms of designing public spatial planning policies, in Portugal, as stated by João Ferro, "collaborative spatial planning processes must become a form of governance" (Ferrão, 2014). Engaging citizens, members of government and other players and interest groups in discussing and considering spatial planning processes fosters the sharing of information and knowledge, social learning and civic and institutional empowerment. Involving citizens in the process can produce better and more suitable outcomes.

The more dynamic the collaborative processes and the greater the concurrence between experts, policy makers, civil servants, different players and citizens, the more efficient spatial planning policies and practices will be (Davoudi & Strange, 2009; Ferrão, 2014). Hence the importance of enhancing civic education processes and the building of civic communities to strengthen ties between the State and its citizens, based on a culture of a more active civic engagement in government affairs and in safeguarding the public interest as regards spatial planning (Peel & Lloyd, 2007).

However, people don't trust in the political model today, which discourages participation and collaboration. On the other hand, dissemination of information and knowledge about development interventions is lacking, alongside society's poor territorial culture (ordinary citizens, political leaders, technical experts and academics). All this weakens citizenship and contributes to further shortcomings in civil society's engagement in the design of public policies (Davoudi, 2012).

1.2. Spatial Planning Policy in Portugal

The Portuguese Constitution enshrines spatial planning as a public sector function, a primary task of the State, and, therefore, it is essential that citizens be clarified as to the concept of spatial planning and the importance thereof. It is essential that civil society be shown that spatial planning does not serve merely for technical assistance in land management, but rather, most importantly, it is a practice underpinned by a set of values that must be part of the national development plan (Ferrão, 2014; Gaspar, 2014).

In recent decades, Portugal has made significant progress when it comes to spatial planning practices and culture, particularly in terms of legal frameworks and active participation in the process of European harmonisation. However, published studies on this process are still lacking (Ferrão, 2014; Gaspar, 2014). In this regard, Ferrão (2014) states that in public policy, spatial planning “is a doubly ‘weak’ policy: its mission is weak, given the discrepancies between the ambitious goals and the conditions to achieve them, and it is weak when it comes to the adverse effects of other policies, given its vulnerability to negative impacts” taking into account spatial planning goals and principles. Portugal’s spatial planning policy is relatively new and prematurely discredited. The technical and scientific community is also very fragmented, although it is seeking to strengthen interdisciplinarity, which itself creates conflict and leads to difficulties of convergence (Campos & Ferrão, 2018).

The infancy and shortcomings of spatial planning in Portugal reflect the poor territorial culture of a part of society, both of citizens and of institutions. A spatial culture ingrained with values, rules and practices based on a “traditional administrative-bureaucratic and technical-rational” still predominates (Ferrão, 2014). These characteristics are of greater concern as this poor territorial culture is combined with a significant traditional spatial planning culture. All this leads to barriers in developing attitudes, competences and practices capable of placing spatial planning at the heart of the national development model. Portugal, therefore, still finds itself in what many authors call “disorderly land-use” (APA, 2008; Baptista, 2008; Ferrão, 2014; Schmidt, 2008).

Ferreira (2007) believes that this situation is related to “accelerated urbanization in recent years”, which is reflected in rapid material, economic, technology and communications changes in Portugal that were not accompanied by a change in mindset. As such, the author recognises that “the Portuguese people do not have an adequate notion and understanding of territorial values. And they mistreat the land. Drastic changes in the way the Portuguese people view, design, use and transform land are needed”. Significant changes are, therefore, required both as regards instruments and planning procedures that implement the “transition from a plan culture to a planning culture”, which expects a greater sense of “culture of territory” from stakeholders (Campos & Ferrão, 2018; Ferrão, 2014; Pereira, 2009).

Until the end of the 20th century, Portugal did not have a clear national spatial planning policy or a regulatory instrument for public spatial planning policies that coordinated land-use, that promoted the engagement of society in designing a public land policy and that promoted a civic planning culture.

2. The National Spatial Planning Policy Programme (PNPOT)

“A well-organised country requires the population to internalise a planning culture. Portuguese spatial planning thus relies on the enthusiasm of technical experts and politicians, as well as the contribution of all citizens.”

(MAOTDR, 2007)

2.1. PNPOT: overview of the process

The Portuguese spatial planning system is regulated by the National Spatial Planning Policy Programme (PNPOT). This Land Management Instrument (LMI) defines the goals and strategic land development options, as well as the national land-use model. The PNPOT is also the reference framework for regional, intercity and municipal spatial planning programmes and guides strategies that effect domestic territory (for mainland Portugal and for the archipelagos of the Azores and Madeira)¹.

The PNPOT was created by the Basic Law on the Spatial Planning and Urbanization Policy of 1998 with the purpose of providing the country with an instrument aimed at defining a forward-looking, cross-cutting and integrated vision of spatial planning and development. Creation of the PNPOT further aims at promoting the coordination and interaction of public sectoral policies on a spatial basis.

Drafting of the PNPOT was only decided in 2002 by the XIV Constitutional Government of Portugal. The final document was approved by the Assembly of the Republic on 4 September 2007, following an extensive period of public debate and consultation, which involved public authorities and representatives of civil society (who sat on the Advisory Committee) (Gaspar, 2007). Once this process was concluded, the implementation stage began, effective between 2007 and 2013. The Portuguese Government (through the Directorate-General for Territorial Management - DGT) is responsible for assessing implementation of the PNPOT and for creating a monitoring indicators system for the action plan and drafting spatial planning status reports (prepared every 2 years)².

In terms of assessment, the PNPOT influenced and hindered spatial planning policies, particularly at regional level, as the design and implementation processes for Regional Spatial Planning Programmes (PROT) in Portugal were based on it. However, during the implementation of the PNPOT, nothing was done in terms of monitoring and assessment, which demonstrates that Portugal still does not have a consistent culture of monitoring and assessing the system and LMIs. It continues to focus primarily on drafting and approving plans rather than reflecting on planning itself. Moreover, during implementation of the PNPOT, engagement of all players was not consistently promoted and a

¹ Basic Law on the Spatial Planning and Urbanization Policy (Law no. 48/98, of 11 August), which sets out the basis for the spatial planning and urbanization policy and creates the PNPOT.

² Basic Law on the Spatial Planning and Urbanization Policy (Law no. 48/98, of 11 August); Resolution of the Council of Ministers no. 76/2002, of 11 April, which determines the drafting of the PNPOT; Law no 58/2007, of 4 September, which approves the PNPOT; General Basic Law on the Public Land, Spatial Planning and Urbanization Policy (Law no. 31/2014, of 30 May).

commitment between stakeholders was not actively encouraged, given the need to implement the Programme's spatial strategic goals.

The PNPOT was only assessed in 2014, when the effective period of the 2007-2013 Action Plan ended (DGT, 2014). Within this scope, several players were consulted and a number of recommendations made for the future, of note: i) the importance of developing strategic spatial benchmarks to improve coordination between the various land management instruments and intensity integrated land-use approaches; ii) the need to develop spatial benchmarks for sectoral policies, namely as regards utility and public services of general interest; iii) the importance of having a governance structure to monitor management of the implementation and operation of the PNPOT (Marques, Veneza, & Maia, 2019).

In August 2016 (Figure 1), the government decided to amend the document in force³, taking into account the drafting of a new action plan for 2030. Amendment of the public spatial planning policy arose due to the need to create an operating, monitoring and assessment system capable of stimulating the implementation of policy, guidelines, directives and measures. Thus, the PNPOT should be considered a strategic benchmark for the territorialisation of public policies and the planning of spatial investments financed by national and Community programmes.

Work to amend the PNPOT was carried out based on a collaborative system of civic and institutional participation. Under technical, scientific and political coordination, the PNPOT was drafted by a large technical team with more than 60 members, including people from the department of national territory, universities and regional coordination committees. Several ministries also collaborated in this process, nearly 40 representatives from the various areas of the Portuguese Government (Focal Points systems), who engaged in multi-sectoral consultation, bringing and debating different views and ways of designing the territorialisation of sectoral policies.

An Advisory Committee, comprising approximately 20 representatives from civil society and businesses organisations and trade unions, associations, professional bodies and Portuguese city and parish associations, also collaborated on the amendment of the PNPOT, bringing to the process the problems and concerns of civil society as regards spatial planning. Thus, over 20 months, a team of about 120 people cooperated continuously, holding more than 150 thematic or cross-cutting meetings (Figure 1).

The PNPOT is a Diagnosis document (DGT, 2018a), focusing on spatial interventions between 2007 and 2017 as a means to update analyses carried out in the preceding PNPOT and taking into account change factors (climate and environmental, socio-demographic, technology and economic changes). It ends with a summary of the major spatial planning issues, reflecting the scientific and technical analyses carried out and the views of the technical community and those of civil society.

The technical and scientific analyses were carried out as a collaboration between producers of scientific knowledge (University of Porto and University of Lisbon) and the technical teams from all

³ Resolution of the Council of Ministers no. 44/2016, of 23 August, establishing the strategic guidelines for the amendment of the PNPOT, through a collaborative and decentralised system based on focal points and an Advisory Committee.

Ministries (most notably the Ministry of the Environment, Ministry of Agriculture, Forestry and Rural Development, and the Ministry of Planning and Infrastructure). The analysis of the perception of spatial planning problems was based on a survey sent to representatives of scientific, technical and political communities (of note, local authorities, city and town councils and parish councils), and to a significant number of institutions representing the corporate and professional world, and society at large (this topic is discussed further below).

The interviews conducted for this study revealed that design of the strategy and action plan to support strategic spatial development goals (DGT, 2018c) was underpinned by active cooperation from the network of focal points (as previously mentioned, a team with different sectoral views). This team designed a Spatial Agenda, divided into 50 Policy Measures, arranged into areas of intervention (Nature Domain, Social Domain, Economic Domain, Connectivity Domain and Spatial Governance Domain) and into Spatial Systems (Natural System, Social System, Economic System, Connectivity System, Urban System and Critical Vulnerabilities), to help boost the effectiveness of the Plan or to improve implementation of spatial policies.

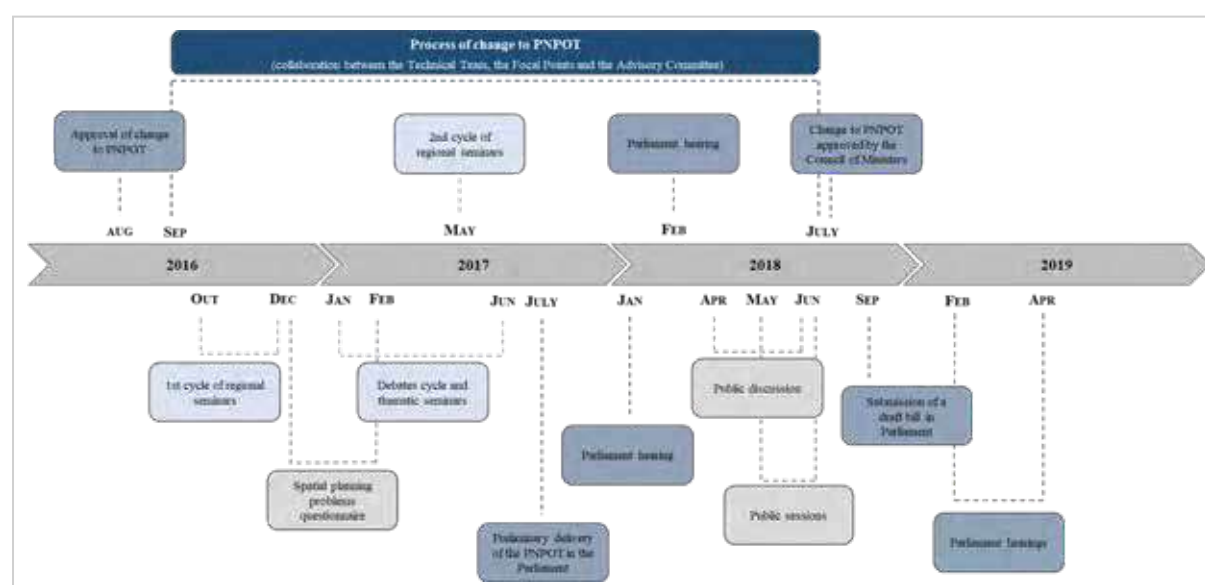

Figure 1: Timeline of the PNPOT amendment process (2016-2019).

Source: Prepared by the authors, based on interviews conducted during the PNPOT amendment process.

In political terms, the process was monitored by the Assembly of the Republic. In January and February 2018, political leaders and technical experts were invited to a public hearing held by the “Environment, Spatial Planning, Decentralisation, Local Government and Housing” Committee, which monitored the implementation of this LMI. These initial hearings were aimed at clarifying and discussing methods to be used in the planning process and to share some information from the initial spatial assessments. Special attention was given to the perception of spatial planning problems, based on the results of the aforementioned survey. Other meetings with representatives from different ministry departments of the Portuguese Government were also held during the process, in which topics specific to their respective areas of expertise were discussed. In mid-July 2017, a preliminary draft of the amendment was submitted to the Assembly of the Republic such that political and

institutional consultation could continue, and the final version drafted, and subsequently submitted for approval (Figure 1).

2.2. PNPOT: to what extent was it a participatory process?

According to the directives of the White Papers published by the Commission of the European Communities (2001) and the Committee of the Regions (2009), the widespread participation during the entire policy process (from design to implementation) will help instil greater confidence in the final outcome and in government arenas (EU, 2001, 2009; Vale, 2007).

The planning process must be participatory, democratic and decentralised. To this end, it is crucial that several opportunities for interaction between all stakeholders be promoted throughout the process (Gaspar, 2007; Healey, 1997). As Gaspar (2007) argues, this effort to strengthen participation and engagement between the various stakeholders must first take place among the team coordinating the process and only then can it be extended to “external” stakeholders, whether ordinary citizens or operators from public or private sector organisations.

Based on these assumptions, the results of the interviews conducted allowed the authors to determine that during work carried out to amend the PNPOT, several public consultation initiatives aimed at civil society were promoted, as well as intersectoral consultation processes. Some of the initiatives are then summarised and an initial assessment is made.

2.2.1. Consulting civil society

Engaging citizens in the design of policies is based on the assumption that all those who are affected by a particular decision should also be given the opportunity to participate in taking the respective decision (Marques et al., 2019).

Just a few months after work began, a national questionnaire survey of the Portuguese population’s perception of spatial planning problems was created, in a dynamic analysis between 2007 and 2017. Based on the 24 spatial planning problems identified in the first PNPOT (Figure 1), the population was questioned (between December 2016 and February 2017) as to the extent to which each of the problems previously identified had been resolved or had worsened.

The respondents were also invited to indicate new problems or problems that had not previously been identified. Published online by central and regional departments of the Central Government, metropolitan areas and intercity communities, municipalities and parishes, business associations, professional bodies, trade unions, higher education establishments and research centres, the survey was widely disseminated and was completed by 7,298 individuals. Worthy of note is that 29% of respondents work in public administration and 23% are linked to universities and research centres. A total of 40% of respondents stated that they are involved in an activity related to spatial planning and/or development (DGT, 2018b; Marques et al., 2019).

The majority of respondents considered that the severity of spatial planning problems has not changed since the first PNPOT (2007), failing to see what has effectively been achieved with this public policy. There is also no apparent awareness of the impact of the design of several sectoral policies, many of which were established at European level. On the other hand, the absence of a spatial

planning monitoring system and the lack of spatial information were highlighted as significant barriers to land management.

Nine problems stood out in negative interventions (exacerbated problem), particularly soil degradation and the risk of desertification, depopulation and demographic and socio-economic disempowerment. As for the more positive changes (resolved or mitigated problem), most noteworthy are water quality degradation and the poor management of water resources, uncontrolled expansion of urban areas, carbon-energy intensity, significant dependence on imported primary energy resources, the lack of external visibility of economic functions, and the lack of resources and basic technical skills for spatial planning.

To keep citizens permanently engaged in the process, the PNPOT online platform was designed (<http://pnpot.dgterritorio.pt/>), where information on the status of ongoing work, seminars, debates and other events held was published, in addition to other documents (reports and legislation).

2.2.2. Promoting thematic and regional public discussions

In keeping with the plan to pursue a participatory process that promoted several opportunities for interaction between the stakeholders involved in the process and society, more than 20 thematic public debates and seminars were held. In an extended consultation processes, key to spatial assessment and designing the spatial strategy, these sessions were attended by a significant number of technical experts and specialists from the different spatial planning areas – geography, engineering, architecture, urbanism, among others –, as well as political representatives and representatives from civil society. It was an interdisciplinary and multi-level discussion.

At the end of 2016 (Figure 1), the first of two cycles of regional discussions were held at the offices of the Regional Development Committees and where matters related to the climate crisis, the urban system, the circular economy, landscape and tourism were discussed. These were primarily of a sectoral nature and brought together specialised experts from different regions of the country.

The second cycle was held in 2017 and focused on the territorial changes that occurred over the past 10 years. This session identified the need to take a forward-thinking approach to the climate crisis, demographic changes and to the dynamics associated with technological change and with the ocean as a resource.

The first half of 2017 also saw several discussions held between experts and thematic seminars, promoted and held by different Portuguese institutions and associations. Public debates were organised by *Associação Portuguesa de Geógrafos* [the Portuguese Association of Geographers], *Associação Portuguesa dos Arquitetos Paisagistas* [The Portuguese Association of Landscape Architects] and *Instituto da Conservação da Natureza e das Florestas* [the Portuguese Institute for Nature Conservation and Forests]. These thematic sessions focused the discussion primarily on three major concerns: what are ecosystem services and how to organise them; demographic trends and the social and spatial impacts thereof; and technological challenges and their impact on the economy.

At the end of the six-month period, a national seminar was held to discuss forward-thinking spatial planning, where several keynote speakers brought insights from the past and designs for the future of spatial development, and discussed key issues for the coming decades: socio-demographic dynamics,

territorial impacts of the climate crisis, assessment of water resources, economic outlook, among other issues.

2.2.3. Promoting a participatory discussion of the proposal

Public discussion, although an intermediate form of participation for citizens (Healey, 1997), in an instrument the scale of the PNPOT, is worthy of note due to the huge number people that comprise the panels and are involved therein (Vale, 2007). In compliance with legal requirements, the PNPOT was put to public discussion between 30 April and 15 June 2018 and the following put to consideration by the citizens: (i) proposal for amendment of the PNPOT (Strategy and Spatial Model, and Action Plan); (ii) opinions issued by the National Territory Committee and the Advisory Committee; (iii) the Assessment report which underpins the strategic options.

During this period, nine public discussions were held countrywide to promote greater dissemination and discussion of the documents as well as greater citizen engagement.

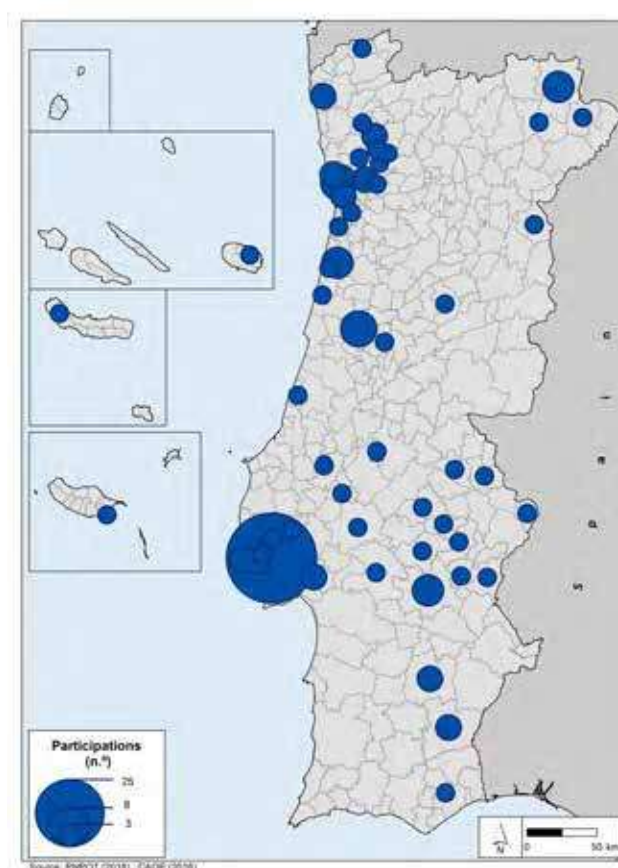

Figure 2: Contributions during the public discussion of the PNPOT, per municipality.

Source: Adapted from the DGT. (2018b). PNPOT | Amendment. Public Discussion - Weighting Report. Technical proposal for the amendment of the PNPOT. 13/07/2018.

The significant participation of organisations representing the sectors and territories, civil society organisations, technical experts and citizens in the public sessions, nearly 1,000 participants, enabled

the debate to be held and the collection of a wealth of input to improve the content of the documents under consultation. The involvement of civil society during the period of public discussion is also reflected in the number of written contributions made, over one hundred, submitted from across the country (Figure 2). According to the Public Discussion Weighting Report (2018), active participation was primarily by municipalities (38%) and private individuals (33%), particularly those with higher education (95%) (DGT, 2018b). Territorially speaking, participation was greater in the municipalities located in the north-west of Portugal, in the metropolitan area of Lisbon and in the Alentejo region.

Taking into account contributions made, all information in the documents that were put to public discussion was either improved or substantially revised. As regards the weighting of contributions made, most were welcome (11.1%) or partially welcome (57.4%), whereas 22.2% of contributions were deemed to already be included in the documents and only 1% of contributions were considered unwelcome (DGT, 2018b) (Figure 3).

Figure 3: Weighting of the contributions made during the public discussion of the PNPOT.

Source: Prepared by the author, based on information from the DGT. (2018b). PNPOT | Amendment. Public Discussion - Weighting Report. Technical proposal for the amendment of the PNPOT. 13/7/2018.

Analysis of the information from contributions made during the public discussion, included in the Public Discussion Weighting Report, highlights that the majority of participants agreed with the contents of the documents (67%), making only suggestions for improvement or minor changes. This analysis identified a few aspects related to the concerns and different views of citizens as regards territorial culture and challenges in spatial planning.

First, concerns related to the ability to implement the governance model envisaged in the PNPOT are highlighted, in particular as the guiding strategic framework for financial options and coordination with the National Investment Programme (PNI) and the next Community framework. The need to boost interaction between the various areas of public policy governance, focusing consultation on the challenges in spatial planning, is also emphasized. As regards the urban system and territorial organisation, society pointed out the importance of cooperation between regions, prioritising network organisation by empowering territorial subsystems. The importance of services of general interest and

investment in the development and quality of regions is also stressed. Stimulating connectivity between the various areas continues to be a major concern.

In short, citizens are being made aware of the enhancement of strategies and policy measures to address some current issues: the urban hierarchy, the country's different levels of infrastructure development, the protection of environmental resources (water and forests), economic competitiveness and improvement of spatial knowledge. The primary focus is on investment and the importance of Community funding, setting aside issues related to the operation, monitoring and assessment of the proposed measures.

On 14 July 2018 (Figure 1), the final version of the documents was approved in an Extraordinary Council of Ministers, with just a few changes requested. The task assigned to the technical team is expected to be concluded at the end of July. The final version of the document (now entered as a draft bill) includes the weighting of the Public Discussion and the outcome of the Council of Ministers. The draft bill was submitted to the Assembly of the Republic in September 2018 for consideration by the different parliamentary groups, which will vote in favour of or against the bill. This is an unusual procedure in Europe, as Portugal is one of the few countries that submits public spatial planning policy for consideration by the Assembly of the Republic. The authors, therefore, believe that it is a procedure that validates the policy measures included in the Action Plan, as they are not only approved by Government officials, they are also endorsed by the parliamentary groups. Approval of the PNPOT in the Assembly of the Republic enacts it as law.

2.2.4. How the Assembly of the Republic promoted participation

Consideration of the PNPOT draft bill by the Assembly of the Republic was, once again, incumbent upon the Committee that oversees the implementation of the LMI. In addition to work meetings and the discussion between its members, public hearings for discussion between the various representatives of civil society and the scientific and technical community were also held. Thus, between February and April 2019, five hearings were held, attended by approximately 20 organisations (civil society and business organisations, trade unions, regional coordination departments, universities and research centres). At the end, the scientific coordination body was heard, followed by the policy coordination body.

An analysis of video recordings provided by the Assembly of the Republic⁴ highlights the ambiguity of the perception of citizens and a somewhat lack of information and territorial culture. The large number of representatives from institutions heard demonstrates the difficulty or inability to combine different topics and develop macro narratives of key spatial planning issues. Testimonials were, primarily, an individual or sectoral view of the problems, often falling outside of the scope of the LMIs, and there were rarely views focused on aligning interests. In the end, several contradictions, territorial cultures and a general lack of awareness of challenges faced were apparent.

⁴ Available at: <http://www.canal.parlamento.pt> (accessed in May 2019).

Conclusions/Final Discussion

Since the beginning of the 1990s until 2011, spatial planning in Portugal, with its ups and downs, developed positively, that is, it went from simply regulating land use and rental policies, to adopting a more strategic and forward-thinking approach. This outlook is, primarily, related to public regional development and environmental policies (most notably the Basic Law of Spatial Planning and Urbanization (1998), the drafting of the PNPOT (2007) and a few PROT). However, since 2011, faced with the economic crisis, positive development stagnated and spatial planning was no longer considered as important as other public policies. This step backwards came at a cost as a result of several factors, in particular: (i) the emergence of spatial planning as an independent domain, historically very recent; (ii) the lack of an adequately widespread and autonomous academic and business community; (iii) Community policies have a considerable influence given the scale of public investment involved, leading to greater public exposure (Ferrão, 2014; Marques & Veneza, 2013; Marques et al., 2019).

In Portugal, the guidelines and strategic spatial development options are outlined in the National Spatial Planning Policy Programme (PNPOT), approved in 2007. Recently (2016-2018), the PNPOT was revised, the process of which is summarised herein. Pursuant to law, and under technical, scientific and political coordination, at the beginning of the process a technical team was put together which, together with a Focal Points system and the Advisory Committee, drafted the Programme's documents (Assessment, Strategy and Spatial Model, and the Action Plan).

Work was conducted by a large team of more than 120 people who cooperated on a continuous basis (over a hundred meetings, dozens of workshops and thematic consultation seminars and debates were held, in addition to hearings held, at the end, in the Assembly of the Republic). Ministries of the Portuguese Government worked in collaboration towards the territorialisation of the policy measures included in the PNPOT Action Plan.

Public participation in the process was also significant. Interview data shows that, during the work carried out to amend the PNPOT, several public consultation initiatives aimed at civil society were promoted, which saw significant involvement. A questionnaire survey of the Portuguese population's perception of spatial planning problems was conducted, which was answered by over seven thousand people. A PNPOT online platform was designed to keep citizens permanently engaged in the process.

Public discussion is one of the legal requirements for participation required for public policies. During this period, public discussions were held countrywide. An analysis of the results reveals significant participation in the public sessions of organisations representing the sectors and territories, civil society organisations, technical experts and citizens, nearly 1,000 participants in total in public sessions and a hundred written contributions with proposals and suggestions.

Following approval of the PNPOT in the Council of Ministers, the draft bill was submitted to the Assembly of the Republic for consideration by the various parliamentary groups. To this end, public hearings for discussion with different representatives of civil society and the technical and scientific community were also held.

Thus, generally, assessment of the PNPOT amendment process is positive as regards the collaborative and participatory process carried out. The concerted effort between the technical team, focal points

and Advisory Committee contributed towards ensuring the final proposal was technically, scientifically and politically sound, as a result of successful cooperation and the sharing of knowledge and lessons learned. Similarly, the period of public discussion (through public sessions and written contributions received) was key to improving and consolidating the final documents. The final discussion and approval by the parliamentary groups of the Assembly of the Republic will enact the PNPOT as law.

However, pressing political agendas and the need to approve the PNPOT in time to influence the preparation of the new Community framework accelerated the process and prevented citizens from understanding the complexity of the documents drafted. The participation of civil society is essential in the learning process and in building the population's territorial culture.

Therefore, in the future, citizens must be encouraged to engage in identifying and solving problems, and in meeting territorial challenges. Spatial planning in Portugal is still not co-creation, the result of significant interaction between the State, civil society, the private and third sector, in a constructive and collaborative process. Society still does not interact or come together around a set of values and consensus. As such, public policy measures for spatial planning should seek to empower society to build these values and consensus, and create environments conducive to processes that effect change. The role citizens play is vital, not only to identify problems, but also causes and possible solutions (Marques, et al. 2019).

Abstract: The significance of spatial proximity in terms of social relations and access to resources have diminished in the recent era while near home environments are still vital components of urban space since they form the secondary territories of urban residents after their homes and constitute the majority of the urban built environment. Albeit, existing residential fabric is under the threat of fast-paced transformations while recent developments emerge in the form of insular subdivisions and residential enclaves. In this context, this research aims to examine the residential environments not through the conventional planning techniques but from the 'insider's perspective'. Hence, the research investigates how urban residents perceive their residential territories in the recent era within different spatial layouts. The extent and content of perceived territorial unit as residential territory, as well as territorial landmarks and also territorial gaps are examined within the scope of the research. In this regard, a comparative case study is conducted in two districts of Ankara, Turkey namely Kavaklıdere and Çukurambar. The results reveal both the consistencies and idiosyncrasies in residents' definition of their residential territories and reveal significant insights for the future planning and design of residential environments.

Keywords: residential environment; human territoriality; resident perception

Transforming Residential Patterns from Traditional Neighborhoods to Urban Enclaves

The significance of spatial proximity in terms of social relations and access to resources have diminished in the recent era while near home environments are still vital components of urban space since they form the secondary territories of urban residents after their homes and constitute the majority of the urban built environment. Although people rather use multiple territories in the recent era with the advances in mobility and communication technologies, near home environments still have a distinct position in daily life and importance in terms of quality of life (Banerjee and Baer, 1984). Yet, as a part of urban restructuring processes to address globalization, intercity competition

* This research is conducted as a part of PhD dissertation of Memlük Çobanoğlu, N. O., 2019, *Human Territorial Functioning at the Scale of Residential Environments*, Middle East Technical University, Ankara under the supervision of Prof. Dr. Müge Akkar Ercan.

and requirements of post-modernity, urban residential patterns and therefore territorial cognition at the scale of residential environment has transformed significantly.

Today, in the production of residential environments, the form of continuous fabric such as in the traditional neighborhoods has left its place to cellular developments and residential enclaves in the form of gated communities and mass housing developments based on economic segregation which neglect the basic principles of sustainability, livability, quality of life and sense of community for the sake of economic progress. In other words, *facility-based organization* of residential areas has left its place to *home-based* ones which in return affected the quality of experience and satisfaction of housing needs in the urban residential areas (Brower, 1996).

In the Turkish case, this transformation on the design of residential environments fostered with the introduction of neo-liberal policies in the 1980s with bigger and more speculative investments in the housing sector which resulted in higher rents, emphasized new meanings on housing and boosted spatial segregation between different social classes becoming more concrete in the form of high-security apartment blocks and gated communities surrounded by surveillance mechanisms (Arıkan, 2013). Another major transformation regarding residential environments in Turkey began with the introduction of Law no. 6306 on Transformation of Areas under Disaster Risk enacted in 2012. Along with the enactment of this law, massive urban transformation processes started in Turkey especially in historic residential areas. There has been controversial use of the law in order to transform these neighborhoods within the central areas for the sake of economic gain through increasing the building heights and floor space rather than creating better living spaces for all. These implementations caused a decrease in the environmental quality as well as infrastructural problems. To sum up, fostering social segregation, decreasing quality of environment, inability to meet human needs, fast-paced transformation, lack of identity, loss of sense of community and alienation can be denoted as the major problems that arose in Turkey with the fast-paced transformation of traditional neighborhoods and development of new areas in the form of gated communities and mass housing developments.

Consequently, the transformation in residential development patterns also caused shifts in terms of territoriality of urban residents. Within these new residential areas, the private domain takes on the role of the old neighborhoods and functions as local group territory in the form of well-equipped homes offering various facilities from laundry to social interactions within single building, while commercial and other services maintained at the neighborhood scale are also transferred to the city scale (Castell, 2010). In this context, the way residential environments are designed not only affected the notions of a sense of community and quality of life, but also transformed the ways residents perceive, utilize and behave in their residential territory. Hence, the extent and content of perceived residential unit as residential territory in the recent era within different spatial layouts will be further assessed within the scope of this research focusing on the two districts in the capital city of Turkey, Ankara both from a traditional and a contemporary residential area.

Residential Environment as Human Territory

Territory is defined as a space whose boundaries are well-defined and well known by its occupants (Sell, 1983). Regarding residential environments, territorial organization of space at this scale is crucial to sustain cohabiting in a delimited space; whereas defining the extent and content of the residential territory have been one of the main tasks of urban planning. Yet, the difficulty in defining

behaviorally meaningful and unambiguous boundaries on residential environments to derive better fit indicators and interventions is associated by Galster (2001) to variations among local actors (households, businesses, property owners and local government) on the perception of its boundaries.

In this regard, there are many measures for designating the boundaries of residential environments such as physical thresholds, statistical areas, character areas (based on building type), community facility service areas (such as the elementary school), land-use and ethnic group concentrations residing in certain locales. Besides, various models have been developed for the designation of the optimum extent of residential territory in planning theory. For instance, the 'neighborhood unit' developed by Perry in the early 20th century based on the principle of an optimal size that corresponds to a five minutes walking distance to a primary school is one of the pioneer models which has later been replaced by a concern for neighborhood functionality.

In this context, official clear boundaries such as census units, planning districts, neighborhoods, or zip code areas are preferred in empirical research due to the availability of large amount of information such as crime reports and housing values, while resident's perceptions may offer a more meaningful and relevant representation of the unit (Coulton *et al.*, 2001) and better express the actual boundaries of the unit in the daily life of its residents (Park and Rogers, 2014). On the other hand, there are also phenomenological approaches that investigate the subjectively designated boundaries that are grounded on the lived experience of the residents (Campbell *et al.*, 2009). In order to determine the boundaries of identifiable subunits, Keller (1968) puts forth a more holistic approach and states that both objective (census tract data etc.) and subjective (respondents indicating the boundaries) indicators can be used simultaneously. Hence, subjective indicators can be utilized to check on the accuracy of the objective indicators. Moreover, Galster (2001) puts forth a framework to indicate that distinct spatial scales of the boundaries refer to different aspects of the neighborhood by presenting '*multi-scaled*' boundaries with respect to bundle of dynamic attributes associated with the residential territory.

To sum up, the type and extent of territorial boundaries of urban residential environments, so called neighborhoods, which have been at the focus of planning studies transformed significantly in the recent era parallel to the changing patterns in the development of residential areas from facility-based to home-based organizations. In this regard, intermingling the conceived boundaries of residents with the administrative boundaries should be at the focus of planning studies in order to better comprehend the complex and dynamic structure of residential environments and to provide better solutions in meeting human needs within these areas. In this context, this research has a phenomenological approach with a schema-based emphasis which tries to investigate the subjective definitions of urban residents on their residential territories in order to grasp their lived experience.

Territorial Cognition at the Scale of Residential Environments

Territorial cognition of residential environments as a delimited area with specific boundaries by its inhabitants is one of the most important preconditions to define that area as a meaningful territorial unit. In addition to this, although territorial cognition is unique to each individual, consensus among the residents and the extent and type of territorial boundaries also reveals the significance of that area as a socio-spatial whole.

Territorial cognitions in near home territories are the perceptions and relations of residents with a particular delimited area, whereas these cognitions may also result in certain affections to the locale such as feelings of security, satisfaction, responsibility, association or problems associated with the area (Taylor, 1988). Hence, territorial cognition of residential areas is often studied in relation to its implications on residential satisfaction, attachment to territory, feelings of safety, development of children and youth as well as environmental quality. In this context, cognitive mapping as a method takes a crucial role regarding the investigations on the extent and content of territorial boundaries of residential environments defined by its residents (Table 1). In other words, cognitive maps are helpful tools in depicting the tacit knowledge of resident's territoriality into research.

Table 1. Some of the previous studies in which an average size for perceived residential territory is investigated.

Author	Case		Average Perceived Neighborhood Size
Lee (1968/1970)	Cambridge		Less than half a mile (>~ 130 ha)
Haney and Knowles (1978)	Green Bay, Wisconsin	Inner city	20 acres (~ 8 ha)
		Outer city	48 acres (~ 19 ha)
		Suburb	155 acres (~ 63 ha)
Guest and Lee (1984)	Seattle		Less than half a mile (<0.79 square miles, ~ 205 ha)
Banerjee and Baer (1984)	Los Angeles	Lower income	0.05 square miles (~ 13 ha)
Lee and Campbell (1997)		Higher income	13 square miles (~ 3.3367 ha)
	Nashville		14.8 blocks
Coulton et al. (2001)	Cleveland		0.32 square miles (~ 83 ha)
Talen and Shah (2007)	Urbana, Illionis		10-400 acres (~ 10 - 161 ha)
Lohmann and Mcmurrin (2009)	Los Angeles suburban area before (1998) and after (2004) the construction of the freeway	City scale before construction	City scale 0.50 square miles (~ 129 ha)
		after construction	0.89 square miles (~ 230 ha)
		Near the freeway before construction	Near the freeway 0.61 square miles (~ 158 ha)
		after construction	0.36 square miles (~ 93 ha)
Minnery et al. (2009)	Brisbane, Australia		Mean max. distance to perimeter: 1500 meters (~ 706 ha)
Pebley and Sastry (2009)	Los Angeles		Several blocks from home
Coulton et al. (2013)	10 cities in US (Denver, Des Moines, Hartford, Indianapolis, Louisville, Milwaukee, Oakland, Providence, San Antonio, and Seattle/White Center)		0.90 square miles (~ 233 ha)
Saghatoleslami (2014)	Mashhad, Iran		36 ha

It is also important to note that, cognitive maps are also affected by exogenous factors. These factors are listed by Evans (1980) under three main titles as; (i) *Different Stages of Knowledge Acquisition* (developmental aspects (children and elderly) and familiarity (length of residence), (ii) *Individual Variables*, (iii) *Physical Features* (environmental structure (such as grid structure of the street layout) and landmarks). For instance, in their study Lee and Campbell (1997) revealed that physical attributes such as size and map complexity differed vastly among how residents define their neighborhoods through a survey conducted in Nashville and denoted this inconsistency as 'respondents' definitional idiosyncrasies. A more recent study conducted by Pebley and Sastry (2009) in sample neighborhoods of Los Angeles also revealed that there is variation among residents' perception of their residential territory with respect to both individual (age, participation in and exposure to neighborhood, socio-economic status etc.) and neighborhood (density, residential stability etc.) characteristics. Besides, the location of the residential area within the urban space is also an important parameter with respect to the size of the perceived residential area. For instance, in their research on neighborhood perception of residents in inner city, outer city and suburban neighborhoods of Green Bay, Wisconsin, Haney and

Knowles (1978) put forth that centrality of the neighborhood differs the content of the territory, such as the number of features and important locations included in the maps, as well as the size of territory.

All in all, cognitive mapping as a method for territorial definition is useful in terms of addressing planning issues at the scale of residential areas since it reflects the residents own experience of place. Yet, not only the boundaries of the territorial unit and consensus among residents but also the content within the defined boundaries provide many inputs for planning interventions. For instance, what is included or excluded from the territory, what constitutes the core of the territory and differences with respect to individual's characteristics may provide fruitful insights for future planning studies. In this context, cognitive mapping is used as a method through this research in order to examine how urban residents perceive their residential territories based on the type and extent of territorial boundaries, landmarks as well as territorial gaps.

Research Methodology and Brief Introduction to Case Study Areas

As discussed in the previous sections, the main aim of this research is to investigate how urban residents perceive their residential territories in the recent era within different spatial layouts. Hence, territorial extent and content of perceived residential unit is examined through a comparative case study conducted in two districts of Ankara, Turkey namely Kavaklıdere and Çukurambar¹.

The first case study district Kavaklıdere² is associated with the early-republican era (formed in the 1950s) and has a continuous fabric as in the traditional neighborhoods, while Çukurambar³ district, which has transformed into a high rise, 'prestigious', luxury residential area after the 1990's with high amounts of gated-communities, is a typical example of contemporary residential developments in Ankara. The case study areas are selected as for being alike in terms of their central location within

¹ The total area covered in the case studies is at the scale of a district which consists of identifiable neighborhoods. Hence, Kavaklıdere district consists of Barbaros, Kavaklıdere and Remzi Oğuz Arık neighborhoods, and Çukurambar district consists of Çukurambar and Kızılırmak neighborhoods.

² Kavaklıdere district took its name from the creek that passes through the area with many poplar trees and had a rural character with many vineyards till the second half of the 1930s. In the beginning of 1950s the district transformed from a rural area to a suburban district with 1,2 storey detached houses and later transformed to a 'modern' residential district with the emergence of high-rise apartment blocks in the late 1950s (Resuloğlu and Altan Ergut, 2015). In the 1970s the district took a sub-center character with many commercial and institutional functions. The district since then functions both as a residential district and a sub-center, while parcel-based transformations started in the area in the 2000s.

³ Çukurambar (a place with granaries - geographically located on a pit land) district used to be agricultural lands till the 1960s with wheat fields and storehouses for cereals. With the mass migrations from rural to major urban areas in Turkey and especially Ankara, Çukurambar district hosted mainly 'gecekondu' (squatter) developments from 1960s till the 1990s. Later, in 1990s the area transformed from gecekondu area to a high rise, 'prestigious', luxury residential area with planning interventions (Durmaz, 2014). Today, Çukurambar is still among the most luxurious and prestigious districts of Ankara.

the urban fabric, articulation to the main developmental axis of the city and besides being prominent examples reflecting the residential area design approaches of their periods as well as for being distinct in terms of patterns of residential development.

During the case study, data is collected through questionnaires⁴ that included two main parts; primarily demographic information is collected from the respondents and later a cognitive mapping study is applied for the assessment of territorial cognition. In terms of selecting the respondents, systematic sampling is used during the questionnaires to obtain a representative sample of households in each district⁵. Consequently, 300 questionnaires are conducted in each district and the results are processed and analyzed both statistically and spatially⁶.

Territorial Cognition of Urban Residents in Kavaklıdere and Çukurambar Districts

Territorial cognition patterns of respondents in Kavaklıdere and Çukurambar districts is further examined in terms of types of designating boundaries, territorial extent of perceived residential environments as well as consensus on these boundaries, shared core of the territory, territorial landmarks and territorial gaps in this section.

Types of designating boundaries

As a part of investigations on territorial cognition, respondents of the questionnaire were primarily asked to draw the territorial boundaries of their residential environment. In this regard, Appleyard (1970) studied the ways in which people structured their cities based on inhabitants' maps of their local areas and the whole city. Hence, the results of his study put forth two main types of residents' maps in terms of structuring the city which are; the maps predominantly using sequential elements (roads) or spatial elements (individual buildings, landmarks, or districts). In a similar manner, the types of structuring that are utilized by the respondents during designating the boundaries are investigated in this research. In this regard, four prominent types of structuring are used by the respondents to bound neighborhoods;

- *Abstract boundaries:* home-centered abstract shapes are drawn by the respondents based on an approximate size
- *Road-based boundaries:* respondents connected the frequently used and well-known streets in order to set the boundaries of the area

⁴ The questionnaires are conducted with the residents of the districts above the age 18 in Kavaklıdere District during April, 2018 and in Çukurambar District during December, 2017.

⁵ Questionnaires are assigned for each sub region in the districts based on the housing density. Later, each street in the sub region is assigned to a pollster in order to provide an even spatial distribution of the respondents.

⁶ The questionnaire responses are processed and analyzed with IBM SPSS Statistics 21.0 and ArcMap 10.4. programs.

- *Function-based boundaries*: respondents draw an abstract form containing the location of certain frequently visited places (parks, schools etc.)
- *Daily-routine based boundaries*: respondents draw the path among the daily used facilities and frequently passed streets combined with the area of these facilities.

In this context, it can be claimed that the road-based and daily routine-based constructions of the respondents are similar to the sequential cognitive maps while abstract and function-based designations resemble more of spatial cognitive maps defined by Appleyard (1970).

In terms of bounding their residential areas respondents used different types of structuring during the questionnaires, while the main type of designating boundaries in both districts is road-based whereas in Kavaklıdere function-based boundaries are also utilized. Thus, it can be claimed that major roads with heavy car traffic are perceived as the prominent thresholds in bounding the residential territories in the recent era in both traditional and new fabrics. On the other hand, identification of well-defined boundaries is a positive aspect of territoriality, however major roads are less permeable elements in terms of connecting the territory to adjacent territories thus becoming separators rather than boundaries.

There are also shared boundaries referred by the majority of the respondents in each district. In Kavaklıdere, most of the respondents referred to Güvenlik Avenue (commercial street) at the west, Esat Avenue at the east, Karum (shopping mall) and Kuğulupark at the south, and Olgunlar Street and Kocatepe mosque at the north for bounding the residential area. In Çukurambar, 1516. Avenue at the west, Muhsin Yazıcıoğlu Avenue (commercial street) at the east, 1505. Avenue at the south and Öğretmenler Avenue (dividing the residential area from the large non-residential uses located at the north of the district) at the north are mainly set as boundaries. Hence, although major streets are conceived as the main boundaries of the residential territory in both cases, existence of a monumental structure acting as a landmark (as in the case of Kocatepe mosque) or a historical site with strong identity (as in the case of Kuğulupark) may also orientate residents by acting as a boundary mechanisms through marking the starting or ending point of the residential territory.

Extent of Perceived Territorial Unit

During the questionnaires, when respondents were asked to draw the boundaries of their residential territory, the term ‘neighborhood’ was avoided and the given base map was almost 3 times larger than the actual administrative neighborhood boundaries in order not to canalize the responses to administrative boundaries of the residential areas. As a result, respondents draw boundaries ranging from 2 to 483 ha. Hence, it can be claimed that there is lack of consensus over the extent of the boundaries among the respondent’s which is defined by Lee and Campbell (1997) as respondents’ definitional idiosyncrasies. However, the drawn boundaries are overlapped to acquire a consensus map of each district (Figure 1) for future inquiries.

In terms of territorial extent, total average size of the perceived boundaries is 75 ha which is similar to the assumptions of planning theory that is shaped by the walking-distance principle (5-10 min walking distance that is 500 meters, approx. 64 ha). On the other hand, the average size of the perceived boundaries in Kavaklıdere decreases to 60 ha while it increases to 90 ha in Çukurambar. In Kavaklıdere, majority of the boundaries (70,7%) are below 80 ha, while in Çukurambar nearly half of the respondent’s maps (42%) are above 80 ha. Thus, it can be claimed that in Kavaklıdere the

perceived size (territorial extent) of the residential area is closer to the assumptions of planning theory that is shaped by the walking-distance principle, while in Çukurambar it exceeds this size and refers more to a driving-distance scale.

Figure 1. Consensus map of Kavaklıdere District (on the left) and Çukurambar District (on the right).

On the other hand, the extent of the boundaries designated by the respondents do not often match with the administrative boundaries. In this regard, the average size of the perceived boundaries in Kavaklıdere District is similar to the size of the administrative boundaries of Kavaklıdere and Remzi Oğuz Arık neighborhoods while it is larger than Barbaros neighborhood. However, in Çukurambar the average designated boundaries are smaller (almost half size) than both Çukurambar and Kızılırmak neighborhoods administrative boundaries. In the case of Çukurambar, smaller perceived size of the residential territory than administrative boundaries of the neighborhoods can be related to the large non-residential uses located at the north of the district such as Çankaya University campus and MTA (General Directorate of Mineral Research and Exploration).

Moreover, in order to measure the impact of individual characteristics on the perceived size of the residential territory further statistical analysis are carried out. According to the results, car ownership and age are the main determinant factors on the perceived size of the residential territory in Kavaklıdere⁷. The larger perceived residential territory by the respondents who own a car in

⁷ In Kavaklıdere district, as a result of the Mann Whitney U test there is a statistically significant difference in terms of perceived residential territory size between car owners and non-car owners ($p < 0.05$) and according to the results of Kruskal Wallis test there is a statistically significant difference ($p < 0.05$) between age groups and occupations.

Kavaklıdere is related with the access to a larger area. Younger and student respondents tend to perceive a smaller area which connotes to a block-scale, this result can be interrelated with the use of multiple-territories in their daily lives and higher mobility of younger people while older and retired people are more dependent on their near-home residential territories in terms of access to certain services and facilities. In addition to these, retired people also tend to perceive larger areas as their residential territory than other occupational groups which still refers to the scale of a walking-distance neighborhood. Thus, it can be claimed that older people, especially the retired, are both more dependent and more actively using their near-home territories resulting in larger areas perceived as residential territory.

In Çukurambar, sex and education are the main determinant factors on the perceived size of the residential territory according to the results⁸. Hence, women tend to perceive significantly smaller areas as their residential territory than men. This can be a result of higher number of housewives among the respondents of Çukurambar whom use their near-home territories more actively while men travel larger distances in terms of reaching to work and other territories. Besides, respondents with graduate degrees tend to perceive bigger areas as their residential territory than other educational levels which can be related to the university campuses located at the surrounding of the area that are often perceived as within their residential territory by the students of higher education.

Territorial Core

There is lack of consensus over the extent of the boundaries among the respondents as discussed previously, while there is a shared 'core area' agreed by the majority of the respondents in both cases. The shared 'core area' connotes to the center of the residential territory most of the residents use in their daily lives and intermingle in terms of social interactions. The size of the core area is similar in both cases; a 20-ha area in Kavaklıdere and a 17-ha area in Çukurambar. The core area of Kavaklıdere district extends along Tunalı Hilmi Avenue from Esat Crossroads to Kuşluköy. Tunalı Hilmi Avenue is a busy commercial avenue on which lots of cafes, restaurants and shops are located and Kuşluköy is one of the most well-known and historic parks of Ankara. On the other hand, the core area of Çukurambar extends along the two main shopping streets (1425. and 1459. Avenues) including also Teoman Öztürk Park. This area contains also many commercial facilities, but dominantly stores for grocery and other shopping as well as cafes and restaurants. The results reveal that, the shared core area depicted by the respondents in both residential districts refers to a nearly 20 ha area with mostly commercial uses. Hence, it can be claimed that the commercial axis at the core of the residential areas act as the center of the districts in both traditional and new fabrics.

Territorial Landmarks

In the second part of the cognitive mapping, respondents were asked to designate what features of the built environment they recalled as territorial landmarks. Hence, respondents were asked to point

⁸ In Çukurambar, as a result of the Mann Whitney U test there is a statistically significant difference in terms of perceived residential territory size between men and women ($p < 0.05$) and according to the results of the Kruskal Wallis test there is a statistically significant difference ($p < 0.05$) between education levels.

‘important reference points in their residential areas such as memorable buildings, streets or open spaces, or places they use while giving directions to someone’⁹. In both cases majority of the respondents were able to identify a landmark in their residential area.

According to the results, the most frequently mentioned landmarks in Kavaklıdere are; Esat crossroads, Tunalı Hilmi Avenue, Kocatepe Mosque, Güven Hospital and Kuğulupark. On the other hand, the most frequently mentioned landmarks in Çukurambar are; Nişantaşı Bazaar (market), Liva Pastry Shop (café and restaurant), Safa Mosque and its park, MTA (General Directorate of Mineral Research and Exploration), Muhsin Yazıcıoğlu Avenue and Arjantin Elementary School. Yet, the higher number of buildings within the most frequently mentioned landmarks and also in the total number of buildings mentioned as landmarks in Çukurambar can be resulting from street names given based on a numbering system rather than actual names which makes it harder to memorize a street as a landmark. In addition to this, majority of the most frequently mentioned landmarks in Kavaklıdere are located within the shared core area derived from the respondent’s maps, while in the case of Çukurambar the landmarks are more dispersed in the district with only the most frequently mentioned landmark (Nişantaşı Bazaar) located within the shared core area.

In the overall distribution among the landmarks mentioned in both cases, 7,7% are open spaces, 4,7 % are an area referring both to a street and an open space (such as crossroads and bus stops), 18,3 % are an area referring both to a building and an open space (such as schools, malls etc.), 21,4% are streets and 47,8% are buildings. Thus, it can be claimed that buildings are the most memorable spatial elements in terms of landmarks. However, the dominance of buildings perceived as landmarks as well as exclusion of open spaces such as parks and squares point out to the lack of open spaces with memorable layouts or characteristics that people can refer to as landmarks in both residential environments.

Territorial Gaps

In the last part of the cognitive mapping, respondents were asked to demarcate and explain areas where they feel uncomfortable or insecure while crossing or areas avoided especially at night in their residential territory. Since, these zones are avoided by the respondents during their daily lives and excluded from the residential territory by the respondents they are referred as ‘territorial gaps’ within this research. The areas depicted by the respondents are later overlapped to designate areas where respondents feel the most uncomfortable. In this context, very few responses were given in terms of territorial gaps during the questionnaires. Thus, it can be claimed that security is not seen as a premise problem within the districts.

Although the number of territorial gaps is low in both cases, there is differentiation between the two districts. In Kavaklıdere, only 41 respondents demarcated an area as fear or discomfort zones among the 300 respondents while in Çukurambar this number increases up to 113. Besides, the most frequently demarcated areas are overlapping only 7 times in Kavaklıdere, while this number also

⁹ Only a few well-known landmarks were pre-existing on the base maps, in order to better orientate the respondent as well as overcoming the difficulties of map reading and drawing by the respondents.

increases to 19 in Çukurambar. Besides, the most frequently mentioned territorial gaps in Kavaklıdere are embassies located at the west of the district along Atatürk Boulevard due to security emergencies occurring time to time as well as bars and restaurants along Tunus Avenue which are declared as discomfort zones due to late closing hours creating noise pollution, parking problems for the residents as well as crowding in the area. On the other hand, the most frequently mentioned territorial gaps in Çukurambar are vacant lots, construction sites and areas on which few squatters are existing. Yet, parks are also referred as discomfort zones due to inadequate lightning and stray dogs.

To sum up, territorial gaps depicted by the respondents living in the districts are areas where the residents feel the most uncomfortable or insecure. Hence, the results reveal that non-residential uses creating infrastructural problems such as parking as well as noise and crowding in addition to vacant lots and construction sites due to security issues are the prominent types of territorial gaps in residential territories. Furthermore, depiction of territorial gaps from the perspective of the residents provides more accurate and relevant insights for the locus of planning interventions at this scale.

In Lieu of a Conclusion

This empirical research aims to investigate residents' perceptions of their residential territories in terms of extent and content through cognitive mapping. The results reveal that, the perceived territorial extent of residential environment is unique for each individual, whereas a consensus area, as in the consensus maps, can be derived from these idiosyncrasies to define the boundaries of the residential territories from the perspective of its residents. The use of consensus maps provides an alternative source of inquiry into urban residential space than conventional solely quantitative mechanistic methods. Yet, consensus maps can be used as a tool for uniting the spatial aspects of the phenomenon such as extent, proximity and layout with the social aspects such as demographic characteristics of the residing population. Besides, consensus maps reveal the accurate representation of residents' experience of space which can guide planners and policy-makers to enhance this experience through the design of the spatial environment.

Besides, although each schema is unique for each resident, overlapping areas as well as differences with respect to individuals' characteristics such as age, sex, education level, ownership or income also reveals important insights. Yet, the weight of these factors differs for each locale. Hence, in order to attain the main aim of urban design is meet the diverging needs of the whole population residing in the same area, the divergences on territorial perception based on individual factors can provide a basis.

Moreover, the results of the study reveal that residents are able to define the subjective boundaries of their residential territory and mention at least one landmark within the area. Hence, it can be claimed that respondents in both cases conceive their residential territory as a meaningful territorial unit. On the other hand, the findings also show that regarding territorial cognition there are both similarities and variances between the traditional neighborhood fabrics and contemporary residential areas. At the cognitive level, the two districts show similarities in terms of the prominent type of designation of boundaries based on major roads as well as the size and main functions within the shared core area. Whereas, districts differ in terms of extent of the perceived boundary of residential territory.

In this regard, the respondents from traditional urban residential environments with continuous fabric (as in the case of Kavaklıdere) tend to perceive smaller units which connotes to a walking distance

scale, while the respondents from contemporary residential environments organized in the form of ‘enclaves’ and comprises mainly of gated communities (as in the case of Çukurambar) tend to perceive larger areas as their residential territory that connotes to a driving distance scale. Based on these results, it can be claimed that in Çukurambar, and most of the newly developed residential areas in Ankara, perception of driving-distance scale territories makes it especially difficult for disadvantaged groups with lower mobility whom also rely on their near-home territories as their primary resource-base. At the same time, the dependence on car transforms the experience of all residents in their near home environments. Furthermore, the perception of residential territory within driving distances can be associated with the design of the physical environment in the form of enclaves with narrow sidewalks adjoined by passive interface zones bounded with high walls or fences resulting in lack of defensibility of space, less number of eyes on the street and decrease the ability of the residents to actively use their near home environments as well as vacant lots increasing the fear of crime and creating unpleasant environments for walking. All in all, based on these findings it can be claimed that the spatial organization of space is a prominent factor causing the differences in territorial perception patterns at the residential scale.

Furthermore, the boundaries designated by the respondents do not often match with the administrative boundaries. Hence, the subdivision of urban areas into smaller spatial (residential) units by planners falls short in explaining the territorial extent of the residential environment. In this regard, in addition to administrative boundaries, that is useful for the availability of a large amount of information, resident’s consensus maps that reveal the lived-in territorial extent of residential space can be used during planning decisions at this scale such as the distribution of services and facilities.

Yet, not only the extent of the territorial unit and consensus among residents but also the content within the defined boundaries, what is included/excluded, provide many inputs for planning interventions. In this regard, consensus maps also reveal the shared core of the residential territory which connotes to the center of the area most of the residents use in their daily lives and intermingle in terms of social interactions. Thus, it can be claimed that the planning interventions at the shared core can result in consequences at the social-group level. On the other hand, the lack of public open spaces both at the shared core of the residential territory as well as the landmarks mentioned by the residents put forth the lack and inadequate distribution of open public territories in both residential environments which is a problematic issue at the residential scale that planning discipline should confront.

In terms of content of the maps, excluded sites, territorial gaps that is the fear and discomfort zones delimited by the respondents during cognitive mapping, are important part of territorial cognition at the residential scale which directly impacts the everyday experience of the residents. Territorial gaps are mainly depicted as non-residential uses resulting in infrastructure, environmental as well as crowding problems in both cases as well as vacant lots and construction sites. The depiction of territorial gaps from the perspective of the residents provides more accurate and relevant insights for planning interventions in terms of revealing the locus of dissatisfaction in residential environments from the insider’s perspective. In this regard, territorial gaps can be seen as places of priority for planning interventions.

All in all, it is also important to note that, this research does not try to emphasize the residents subjectively defined boundaries as a sole determinant of the territorial extent of residential

environments, but rather tries to put forth that in addition to conventional methods the use of resident's perceptions of their lived space can reveal different insights for the decision makers regarding spatial developments. Hence, rather than relying on a single basis, planning studies can use a diverse amalgam of approaches to unfold the nature of the lived experience of the environment in order to guide future interventions and production of new residential patterns more responsive to diverse human needs.

The Characteristics of the Working Place of the Creative Class: The Case of Fashion Designers in Istanbul Nisantasi

Gulsen Pelin Olcay¹, Hande Mengin²

¹*Istanbul Arel University, pelinolcay@arel.edu.tr*

²*Istanbul Arel University, handemengin@gmail.com*

Abstract: Development of the fashion design industry in Turkey has gained momentum since the 1990's. Nisantasi, where there are many luxury garment stores and ateliers producing haute couture evening dresses, is the neighborhood where most of the fashion designers have an office. On the other hand, fashion designers are part of the creative class. The creative class has high knowledge and skills, as opposed to unskilled workers engaged in routine work in industrial plants. This working class, which works flexibly, needs different working places from the classic work offices. The researches in the literature related to the design criteria of these work places are insufficient. In this study, fashion designers' offices in Nisantasi were examined and both environmental characteristics and interior features of the offices were analyzed. Face-to-face interviews were held with designers. In these interviews, the reasons of clustering of the designers in the region, the environmental, physical and social factors affecting their creativity were questioned. The answer to the question of how to design the ideal office where fashion designers can exhibit their creativity was also sought. This research provides design criteria for the offices of fashion designers as well as location criteria of them.

Keywords: Creative Class, Fashion Industry, Working Place of Fashion Designers, Nisantasi

Introduction

People who work for the purpose of creating meaningful new forms and who earn income because of this work are named as Creative Class by Richard Florida (Florida, 2002). Unlike the unskilled or semi-skilled blue collar workers who perform routine, monotonous and tedious work, these workers do the work that requires skill, knowledge as well as high technology.

The creative class works out of traditional working patterns and works under more flexible working conditions. Working place of this class also differs from classical working place. For this purpose, this research seeks an answer of the question about how to design working place of the creative class. It focuses on fashion designers, a part of creative class, and their working places. In the research, it is aimed to find out designing criteria for the working place of them by examining the factors effecting them, their requirements, their needs and their current working place. The research focuses on the fashion designers in Nisantasi district of Istanbul since 22 of the 71 fashion designers registered to the Association of Fashion Designers are located in this area. Face to face interviews were made with 8 of 22 fashion designers in Nisantasi, and their offices were examined.

Creative Class and Creative Industry

Various definitions have been made about creativity. Creativity is to produce new things, ideas or assets. Therefore, creativity is the principle of innovation (Sundgren and Styhre, 2003). Creativity is the whole of the talent, hunter and motivation needed to deal with the problem. Dobbins refers to creativity as a skill that can be learned and developed (Dobbins and Pettman, 1997)

Three essential criteria for evaluating the creative idea are defined. They are: novelty, value, and surprise. Novelty is a measure of how different the idea is from existing similar ideas, but it is different in its value. Value is a measure of how the potentially creative idea compares to other ideas in its class in utility, performance, or attractiveness. To distinguish this from novelty, value is a measure of the idea's utility rather than a measure of how its description differs from other ideas in its class. The measurement for surprise has to do with the recent past and how we develop expectations for the next new idea. This is distinguished from novelty because it is based on changing the expected next difference (Yassa et al. 2016).

Parallel to the technological developments in the 20th century, concepts such as creativity, innovation and meritocracy started to come forward. Workers have not been seen as tools only, but their skills and creativity have gained importance. This has led to the need for organizational, physical and managerial change in small and large scale companies. In the previous years, various definitions have been made for the working class which used information as input. Richard Florida defines the knowledge workers who work for the purpose of creating meaningful new forms and earn income from this work as Creative Class. In its original classification, Florida divides the creative class into two "creative core" and "creative professionals". Scientist, engineers, academic researchers, writers and poets, artists, actors, designers, architects as well as editors, researchers, analysts form the creative core. High-tech sectors, financial sectors, health professionals, and business management fall into the class of creative professionals (Florida, 2002).

Creative class prefers some certain urban spaces to work and live. Florida states that "... tolerance is the key factor in enabling places to mobilize and attract technology and talent ". According to Florida, it is the quality of places that attract creative people and because of their presence it attracts high tech industries and cultural industries. The central idea is that "... tolerance and low entry barriers to human capital helps to attract talent and that talent is in turn associated with high technology industry and regional growth " (Florida, 2005). Westlund and Caledoni-Lundberg have given a list of factors that are effective in making urban spaces appealing to the creative class. Accordingly, a region must contain the following factors to attract the creative people (Westlund and Calidoni-Lundberg, 2007) :

- A life style with a wide range of recreational activities
- A large and busy labor market that facilitates business mobility,
- Tolerance to different ideas, lifestyles, cultures and ethnic groups,
- Cultural authenticity of the region or place,

In recent years, the term of "Creative Industry" is a concept that is frequently mentioned in various industrial fields within the framework of creativity and economy. The first use of the concept of

creative industry is based on the new economic policies of the British government in the mid-1990s. In 1997, the newly elected British Labor Party Government, led by Tony Blair, argued that the economic value of areas related to creativity and culture is not sufficiently understood, and that the industries involved in these fields are important sources for creating jobs and raising welfare. In this context, the government established the Department of Culture, Media and Sports (DCMS). According to DCMS, the sectors that become the creative industries are "advertising, architecture, art and antique market, handicrafts, fashion design, interactive entertainment software, music, performance arts, printing, software, television and radio" (Demir, 2014). Creative industries are the cycles of creation, production and distribution of goods and services, in which creativity and intellectual capital are used as main inputs. It provides profits from trade and intellectual property rights. It focuses on art, and moreover, it is related to the sectors of art, service and industry (UNCTAD, 2008; Erkayhan, 2015).

Development of the Working Place and Working Place of Creative Class

It is possible to define offices as open, closed and hybrid office. Open offices are the functional working spaces in which portable unsupported divider panels do not rise up to the ceiling. One of the main objectives of creating these offices is to accelerate communication, interaction and workflow among employees (Kaya, 2010). Increased communication between the steps in the hierarchy, increased productivity in the flexible space and cost savings are the positive effects of the open office on companies (Wagner and Watch, 2017). But these offices also have some disadvantages, such as gathering of many workers together, increased noise, and loss of privacy. On the other hand, closed office is the working unit which is surrounded by walls, and personalized by the workers. Closed office systems are the most appropriate design approach for companies with high level of privacy requirements. Communication in closed office systems is weak and controlled (Kaya, 2010). The other concept is hybrid office. When disadvantages of open and closed offices are regarded, architects have headed to the hybrid office where both open and closed spaces are integrated. However, with the development of technology and the change of the labourforce, new types of offices have been needed.

Actually, physical characteristics of the working place have changed for last two century. The transition to the service industry sector has played an important role in the development of working place. New complex business activities have required more sophisticated solutions and management systems in order to improve performance of employees. Essential changes in the design of working place started in the very beginning of the 20th century. "Scientific management" principles developed by Frederic Winslow Taylor led to the industrial Fordism model adopted by non-industrial businesses. This new work model for industrial settings promoted the concept of breaking down labor processes into detailed tasks to improve efficiency. This new way of work had a huge influence on architectural as well as interior design (Cagnol, 2013; Albrecht and Broiks, 2000). In the subsequent decades a new spatial tendency arose in Europe. In 1960 Wolfgang and Eberhard Schnelle developed a new concept for workspace design called "burolandschaft" or "office landscaping." The initial intention was to promote teamwork and collaboration with new arrangements designed to fit patterns of communication, informal layouts, environmental psychology, staff satisfaction and performance, open space, flexible furniture, rising equity and diminishing hierarchy. In 1990's, the worker was no longer perceived as a person who would fulfill his duties, but also as an individual to be dealt with. So, it became the responsibility of the employers

to ensure healthy working conditions (Albrecht and Broiks, 2000). Technological progress has a significant impact on the design of the working place. It has not only transformed the qualifications of the furniture and engineering solutions, but also reduced physical distances by strengthening communications (Obispo, 2016). In the late 1980's to 1990's the rise of technologies started the post-industrial era. The internet was a great engine for many start-ups that would grow overnight. Unpredictable markets and patterns required teamwork for productivity and flexible spaces to adjust to changing. Another important feature resulting from the introduction of the internet to the workplace was a freedom to perform work tasks without the attachment to geographical location. Many new work modes and concepts were introduced and applied due to increased mobility and fluidity (Myerson et al. 2010; Albrecht and Broiks, 2000). Since the year 2000, IT companies have been trying to push for a more creative, innovative office design (Cagnol, R. 2013). Working spaces have turned to undefined virtual and physical places from familiar and predictable places. These contemporary offices have mixed workforce and present different environment. There is a wide discussion about how to design places where workers using creative knowledge operate, and which strategies to be used in the organizational management. In this contemporary offices, some unusual spaces are come across, such as sleeping rooms, social activity spaces, sport and entertainment areas (arkiv.com.tr). The fact that different industries have similar types of workspace with various characteristics makes it difficult for a designer to figure out particular requirements for each case. Even narrowing down to creative knowledge workers as a potential clientele, architects might have to provide suitable physical setting for activities varying from advertising, video games, business incubators, think-tanks and sciences. Thus, in last decade working place such as research institutions, incubation centers, and innovations centers have increased significantly all over the world (Obispo, 2016).

The rise of information communication technologies has led to the formation of an entirely new social group, which Florida refers to as the "creative class". Florida implies that this working class needs ability to perform tasks as well as creative thinking. Moreover, they can also be professionally associated with the economic structure called as creative industries. Since creativity is not a phenomenon that occurs during working hours, the creative class prefers to work and produce in the time they are most productive. The opportunity of working out of the office, lack of dress code, working with a team of open-minded individuals are other motivation sources for these individuals. Working hours and duration of work do not make any sense for them. On the contrary, it is important to adjust the working hours to themselves and to improve the quality of work and to deliver the project on time (Florida, 2002). For this reason, there is a need for working places where the creative class can motivate, work with self-giving, create, and produce. These places will lead to new ideas. Instead of an organization where people are forced to do the same thing from morning to evening, it is absolutely necessary for a creative environment where they can be active and mobile. The main purpose of the modern office concept is to eliminate the hierarchy, flatten the pyramid, and thus obtain a pleasant and productive working environment.

Physical work areas affect the success and creativity of users. Creativity not only depends on the personal characteristics of the creative worker, but also on the physical environment they encounter and work with (Dul et al. 2011). A suitable physical environment with appropriate light, furniture, space and ventilation can promote creativity, and an environment with noise, heat, insufficient lighting and a lack of space can hinder creativity (Yassa et al. 2016). On the other hand, not only the

building space that is worked, but also the urban space that is lived affects creativity. The city has become a place where creativity has been created, implemented and at the same time a place affected by the creative activities done. Economic activities based on creativity in urban environment depend on interrelated various factors. In this sense, it can be said that the creative space creates differentiated interaction networks in the space and establishes relations with related industrial activities (Copercini, 2015).

In the literature, the studies on the working place of creative class are quite limited. There are researches that deal with the context of creativity as a psychological and social environment, but it takes only a little consideration of the physical context. In addition, The most debated things in the literature are ergonomics, spatial arrangements of offices, environmental psychology, sociology, architecture and innovation (Yassa et al., 2016). What are the design criteria of the working place of creative class? As the creative class covers a large number of different sectors, the working spaces of fashion designers are discussed in this study.

A Creative Industry: Fashion Design

The concept of fashion, which is coming from the word of "modus" in Latin, and means unlimited, has effect in many areas. Sproles defines the concept of fashion as transient cyclic phenomena adapted to a specific time and situation by the consumer. Although he defines clothing as the classic product of fashion, he also states that fashion is related to the aesthetic choices of consumers from car to house, from eating to music (Sproles, 1981). It is stated that various aspects of the people's lifestyles in modern consumer societies reflect social status and success. In this context, fashion is effective on all products that are visible, such as cell phones, cars, watches. According to Simmel, the fashion can contain all aspects and conceptually all contents (Simmel, 2003). Moreover, every clothing, art, behavior or appearance form can be in fashion (Ertürk, 2011). In today's sense, fashion is defined as the way of dressing especially followed by women. It is related to the life style.

In Western Europe, fashionable dressing behavior has continued since the Middle Ages. The basic function of clothing fashion from the Middle Ages to the New Age is to specify the social class. The political power centers such as the Burgundy of the Middle Ages, the cities of Northern Italy during the Renaissance and then the French Palace were very influential in the fashion field. In this period, the people involved in the fashion process were also limited, such as well-educated people, and the royal family. In the 19th century, garments were produced with industrial methods. The increasing number of different social groups have begun to be effective in the development of fashion. This development has been managed and supported by modern mass media from fashion centers such as Paris, Milan, New York or Berlin (Evecen, 2015). Until the Industrial Revolution, the fashion of clothes for the aristocratic class was on the streets of all worlds. However, these status differences have disappeared and been replaced by the economic war of the brands (Çeliksap, 2015). In the 1920s, the role of women in capitalist societies were changed considerably, and great designers such as Chanel provided a simplification of clothing. The aristocratic world of glorious consumption collapsed and fashionable, luxurious clothes for women were used only at official events. In the 1950s, fashion got closer to ordinary people. A more pluralistic fashion industry were created, escaping the tendency to couture (Aage and Belussi, 2008). The democratization of fashion took place in the 1970s. It was characterized by the success of low-cost manufacturers such as Levi's, and the introduction of fashion into mass markets.

On the other hand, fashion is one of most criticized concepts. Some researchers argue that fashion, as a social phenomenon, targets identities in capitalist society and uses social identities that have a variable structure both aesthetically and economically. In capitalist societies, the effect of fashion is very much felt. In these societies, individuals identify themselves and their identities through the clothing they buy and use in their daily lives (Evecen, 2015).

Textile design, regardless of the purpose, primarily refers to a process that involves the act of creating. The final product is a unique proposition of the designer as a result of complex processes (Dinçer, 1997). In his design process, the designer reveals his product by regarding the social, cultural, technological, economic and aesthetic values of the society. He interprets these expectations of the society according to his own. He also regards the fashion trends determined by international fashion centers. Determining fashion is primarily a design work (Dumanlı, 2014). On the other hand, innovation is the main source of fashion. When searching for innovation in the field of fashion, it is necessary to build a bridge between the past and the future (Çeliksap, 2015).

Development of Fashion Industry in Turkey

Textile is an old sector with a long history in Turkey. For centuries, fabrics unique to local areas have been produced using traditional methods. However, the fashion design industry is very new sector for the country. For example, while fashion was spoken in 1700's in France, fashion designers who engaged in their own design were be able to be trained in 1990 in Turkey.

Pattern designs of woven fabrics were prepared in the 16th century in Ottoman Empire. This means a process of design in the real sense. However, Ottoman clothes were cut without any distinction between men and women for centuries, and it was impossible to talk about fashion design. In the West, the material, form, design methods and techniques of constantly changing men's and women's clothing were the subjects of fashion history. It is known that the Western influence was gradually increasing in both life style and clothing habits of Ottoman society from the nineteenth century onwards. But the end of this century, fashion phenomenon experienced in Turkey was developed with much curiosity and sense of imitation, unlike the process based on production in West. In the country, it is possible to talk about a fashion consumption for a particular group in the late 19th century and early 20th century. However, fashion was not developed as a sector, and production similar to production in centers such as Paris and London could not be mentioned. In Istanbul, where fashion consumption was at an advanced level, it is known that there was very little tailor-made sewing. Even though it did not develop as a sector, fashion curiosity were seen in port cities like Istanbul and Izmir until 1922, and then in Ankara (Şahin, Y. 2009). On the other hand, the development of fashion design education was slow and limited. Designers started this work either by studying abroad or by being educated within a master-apprentice relationship.

There were some fashion designers who stand out in the Turkish fashion industry until the 1990s. These designers were mostly doing haute couture. In the 1990s, competitions such as the Koza Young Fashion Designers Competition were the major milestones in the fashion design sector. These competitions led to the emergence of young designers who were trying to create their own brand, creating their own way, designing models except haute couture.

In 2000's some important developments accelerating the development of Turkish fashion design sector were lived. New generation fashion designers organized festivals and events, such as Galata Fashion, and international meetings, such as Istanbul Fashion Week. In 2006, the Fashion Designers Association was founded by 7 fashion designers who had contributed to the development of the Turkish fashion design sector. The purpose of the association was that the Turkish fashion design sector played a decisive role in the formation of world fashion trends. Moreover, Turkish ready-to-wear firms started to prepare collections with Turkish fashion designers. Domestic clothing brands offered the collections of Turkish fashion designers for sale. These developments have caused the target group of the fashion sector not to be only high-income group and the sector has started to address different segments of the society. The 2000's was a period when Turkish ready-to-wear suppliers that exported abroad were trying to provide design services to their foreign customers in order to increase their competitiveness. Some of these Turkish ready-to-wear suppliers started to work with Turkish fashion designers, which contributed to the development of the sector. Therefore, it can be said that 2000's is another turning point for Turkish fashion design sector. Today, the biggest markets of Turkish fashion sector are Europe and America.

Reasons of Location of Fashion Designers in Nisantasi

It is striking that the district where the fashion designers in Istanbul choose mostly has been Nisantasi. According to the data of 2018, 22 of the 71 fashion designers registered to the Fashion Designers Association are located in here (Figure 1).

Figure 1: Location of Fashion Designers' Office in Istanbul

As Istanbul is the gateway of fashion and textile opening to the world and a metropolis that has international relations, fashion designers choose to locate in Istanbul. The majority of these designers are in Nisantasi despite the high rental rates. It can be talked about a fashion design cluster in

Nisantasi. The most important suppliers of these designers are the fabric and the accessory suppliers settled in this area (Figure 2). What are the dynamics that cause the fashion designers to cluster in Nisantasi?

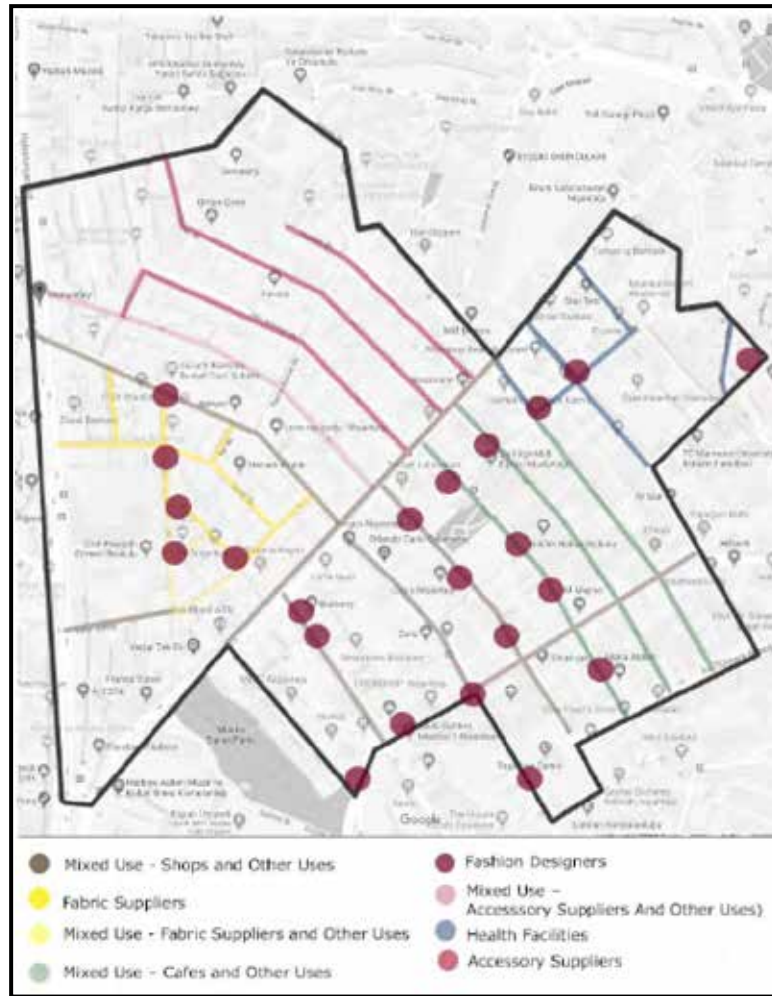

Figure 2: Fashion Designers Cluster in Nisantasi

Nisantasi is one of the neighborhoods where upper income groups live (Öncü, 1999). For many years, the district has been a preferred by trade and industrial sectors, such as garment and textile. Shopping centers opened along the main streets also supported this process. Today it is observed that Nisantasi resembles an open-air shopping center. It does not only addresses the district, but also the whole city. The district has become a field of activities for shopping tourism with the interest of world famous stores selling luxury products (Akbayar, 1993). In Nisantasi, beginning from the 1970s and 1980s, the tailors and then the fashion houses has begun to take place. These fashion houses has begun to sew haute couture products in the form of evening dresses and wedding dresses. Since the 1990s, the new generation of fashion designers have also concentrated in this neighborhood. In short, the presence of potential customers as well as the presence of fabric and accessories suppliers in the region has initially been influential in choosing of location of fashion designers in Nisantasi.

The values of the creative class, individuality, openness and difference are the core values of fashion designers in Nisantasi as well. Fashion designers in Nisantasi prefer work individually. The main

reasons for this are being free in their design, lack of working hours and working pressure. Although their offices have rules, these rules can be stretched. These values are effective both in the location of their offices and in the design of office spaces.

The openness, a value of the Creative Class, is one of the factors influencing the location choice of the designers. Nisantasi is a neighborhood where people from different religions and races live together. Many different people living here have learned to live together. Most probably, the designers have chosen to live in an area where different cultures can coexist and people accept each other as they are.

Being a part of the network formed by the designers in Nisantasi and providing information through this network is another reason for clustering of designers. For the designers, having place in this network is important not only for information sharing but also being visible in the sector. Buyers can make comparisons between products in this region where a large number of designers are clustered.

Inner Space Analyses of Fashion Designers' Offices in Nisantasi

In the interior analysis of design offices, the structure and function areas of the offices are examined (figure 3). Designers were asked questions about the initial state of the office, present state of it and what kind of changes they made. The designers were also asked to define ideal working space for them.

Most of the designers' offices are located in 40 or 50 year-old buildings. Designers are tenants in these buildings. Therefore, the changes they make in office space are mostly related to decoration. They did not change the structure and kept the structural elements such as walls, windows and doors as they were. Some designers chose wall colors in light tones to create a larger perception because their offices were small. Nearly all of them are well lighted. Both natural and artificial lighting are used.

The designers' offices have many accessories and objects, many of which have their own design. Some designers have reused many things that have meaning for themselves by transforming them. They have given life to many objects such as a childhood bike, his own drawings and paintings, a hand-woven rug, a converted chandelier, and a vintage table from the closet doors of his grandfather's house. Many items in many offices have a history. One of the most important accessories in these offices is the hangers. The hangers are also functional accessories. In their offices, designers often use movable hangers to expand the venue in meetings, fashion shows, etc.

While taking part in Nisantasi is beneficial for designers, using the old buildings in Nisantasi as a working place brings some disadvantages. As designers try to settle on existing old buildings, it is observed that the dimensions of the space are not suitable for their use. Generally, the connection between the spaces and functions are weak in offices. Storage and workshop areas are often inadequate. Some designers are forced to carry out basic operations such as manufacturing outside the office areas (figure 3).

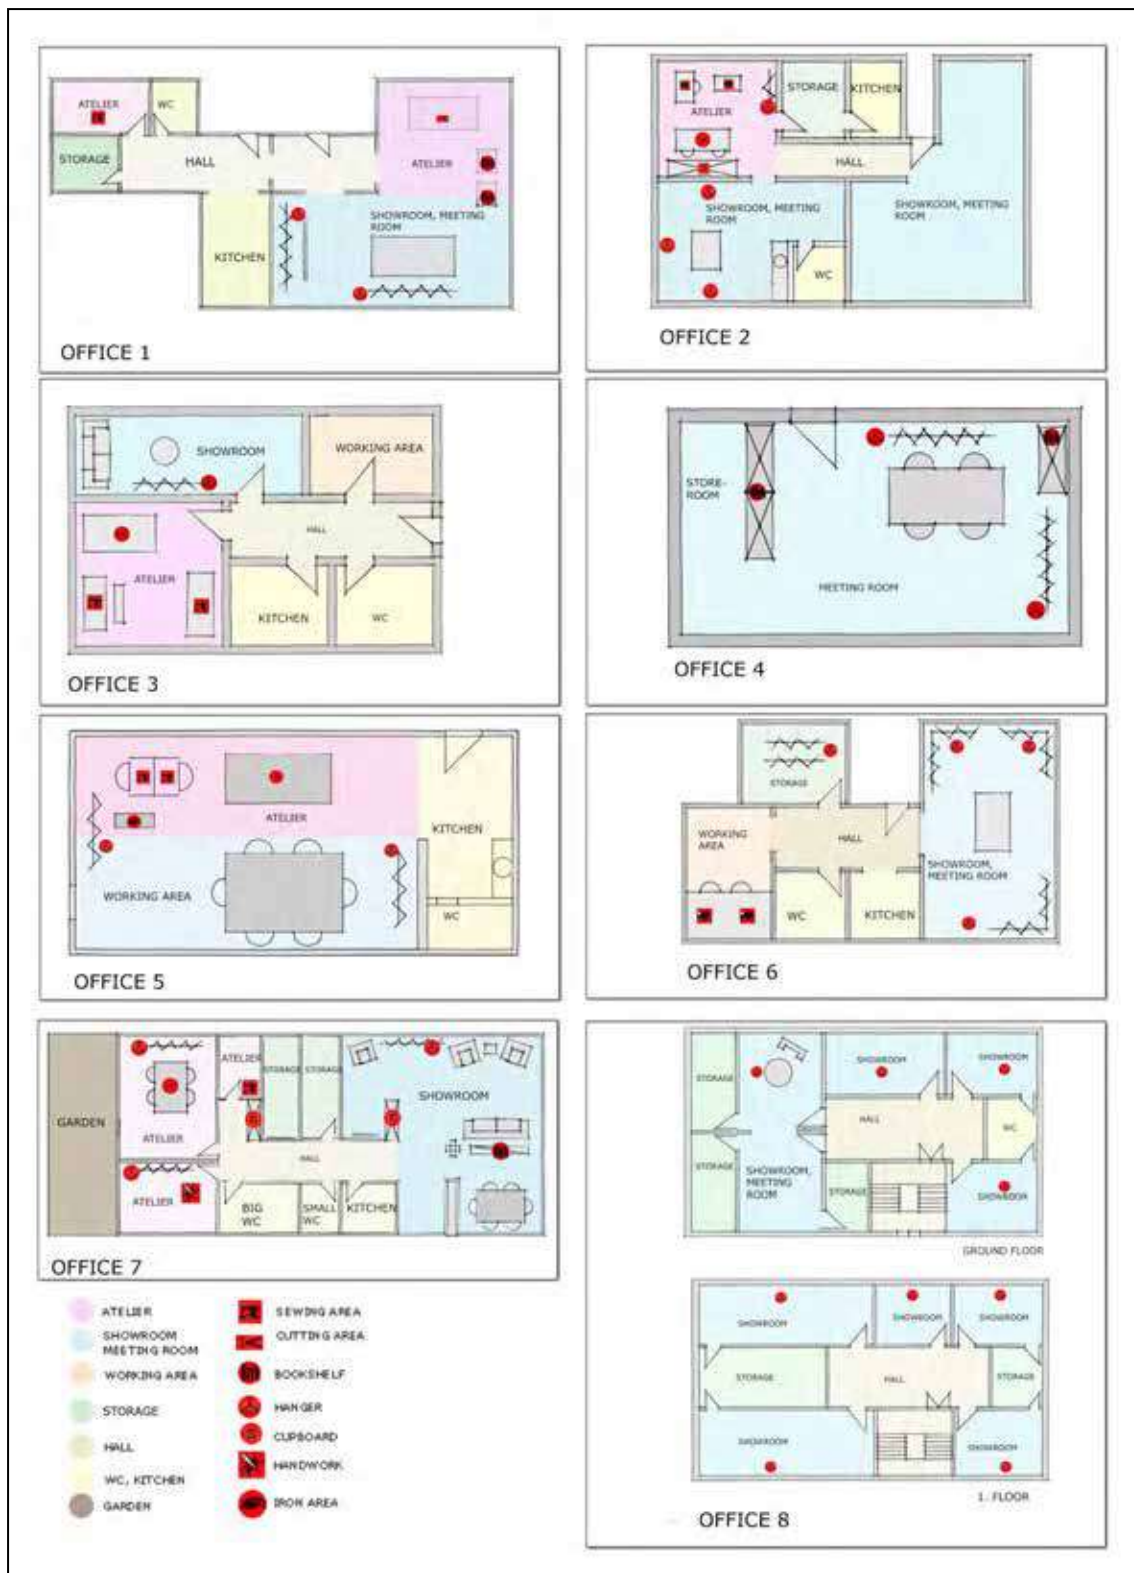

Figure 3: Plans for Current Office

Designers basically carry out two activities; design and production. Only one of the designers interviewed has a workroom in his own office. Other designers have no separate workroom. Most designers do not need a workroom in their offices to design. However, most of the designers realize their production stages in their offices. Some of the designers have an atelier outside of Nisantasi and

some designers make their production to manufacturing firms. All of the designers emphasized that it is important to have an atelier at the office and some state that they need larger ones. Actually, manufacturing is a part of their designing process.

Showroom is one of the most basic places in offices. Generally the collections of the designers are exhibited in these showrooms. Showrooms are the places where designers display their products to their customers and carry out their marketing and communication activities. In addition, showrooms can be used for multiple purposes such as meeting and design.

In the offices of the interviewed designers there is no storage room or the existing ones are small. Almost all of the designers stated that they needed large storage rooms where they could store old season designs, accessories and fabrics.

Since the design processes are flexible and they are not time dependent, it is examined whether there is accommodation in offices. Designers do not have accommodation in their offices. Some designers think that having accommodation will reduce the yield. It can be thought that the fact that the design activities are mostly done outside the office eliminates the need for accommodation in offices. However, a kitchen is located in almost every designer's office.

Office Design Criteria of Fashion Designers in Nisantasi

According to the observations and findings, for the fashion designers, the design process is a process that involves the design and production stages. In fact, the production process in which the design turned into product is an important part of the design process. Therefore, design and production are two basic and nested processes.

Designers mostly carry out the design activities out of the office. This is due to the fact that design is an activity independent from time and space. 7 of the 8 fashion designers interviewed do not have their own design unit in the working place. Some designers have said that they can make design everywhere, because the things they are inspired by are independent from places like legends, stories and Anatolian culture. Istanbul inspires some designers. Some of the designers work on the bus, even in any cafe. There are designers who do not even need a paper and pencil, and make their design with their smart phones. One of the designers expresses that he is inspired by films and books, he can design only while watching movies and reading books and therefore does not need a space to design. Some designers prefer to design at home. Visitors coming to their offices during the day also prevent some designers from focusing on design. For a variety of reasons, the majority of designers make designs outside of working place and do not need any space to design. But the production is a part of design, and designing process continues in atelier. Thus, the production phase is one of the main activities in the offices. There is a large atelier in the ideal office of the dream of all the designers interviewed. Because if there are large atelier in their offices, they will be able to realize the whole production, but also have the chance to interfere with the design in production when they want. 6 of the 8 designers interviewed have atelier in their offices. But they all find them insufficient. Designer 6 who has no atelier in his office stated that he should definitely have a atelier in his ideal working place. Designer 4 has an atelier in his office in Çatalca, another district in Istanbul, but he believes that all these units must be intertwined.

One of the most basic function areas in the offices is the showroom. Almost all of the designers used the showroom and meeting room together and not complained about this situation.

Design offices need large storage area. Because there are not enough spaces to store fabrics, accessories, old season products, and prototypes. Designers underlined that it is very important to have a storage room in their offices.

There were no accommodation areas in the offices. 7 of the 8 designers think that there should be no bed and accommodation units in the office. Only 1 designer stated that they should have a unit where they can relax in their ideal places, and that they need open or semi-open spaces where they can spend time in their offices.

In short, fashion designers dream of large working spaces that they can design while they are producing, that they can intervene in every stage of production. Because the creators' creativity continues in the production phase. If the design process ends when production starts, there will be less chance for them to produce the best product as they do not have the chance to intervene.

On the other hand, according to the designers, in order to exist in this sector and to be able to market their designs, they should locate in Nisantasi, which is the heart of the fashion. This shows that, for the designers, the location of working place is important as well as the interior features of this space. In the design of the designer's working place, urban scale is as effective as the building scale. It is quite difficult to find a large office in a built-up area like Nisantasi. For this reason, some designers had to try to fit into their existing work places. Some of them contracted with companies outside the office to realize the production part of their designs. The others used a few offices, one in Nisantasi and the other in another district.

At the end of these evaluations, 3 types of fashion designer's office schemes can be presented, in which all the units are located in Nisantasi, or some of them are located in the districts outside Nisantasi. Different alternatives can be produced by changing the locations and dimensions of the functions according to the needs.

1. Integrated Fashion Design Office in Nisantasi

Although it is very difficult to find a large office in Nisantasi, a scheme for an integrated office in Nisantasi is created. In this scheme, all activities are carried out in a single office in Nisantasi (figure 4). The design space in the office can also be solved in a separate space or intertwined with the showroom. Design space is not compulsory. The biggest venues are solved as showrooms and atelier. If a design unit exist, it can be associated with both the showroom and the atelier. Storage area is a need in the office. Both the atelier and the showroom have their own storage.

Figure 4: Scheme1 - Fashion Design Office That Has Showroom and Atelier in Nisantasi

2. Partial Fashion Design Office

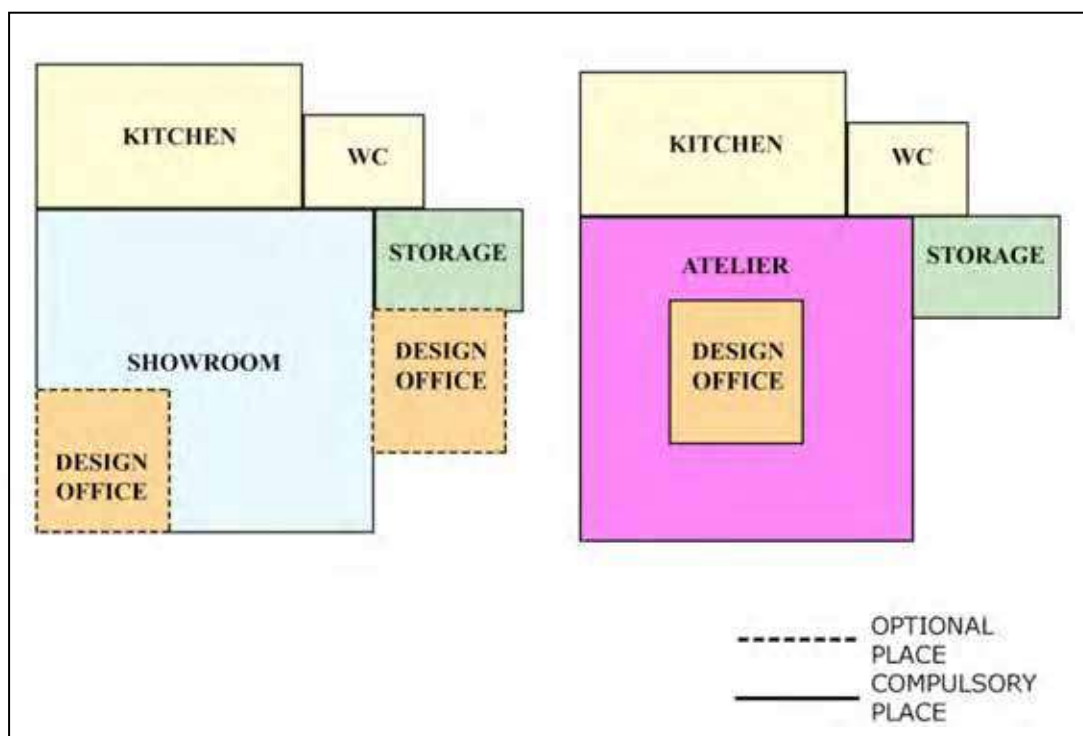

Figure 5: Scheme 2 - Fashion Design Office That Has Showroom in Nisantasi and Atelier outside of Nisantasi

Scheme 2 is created for the designers, who locate their showrooms in Nisantasi due to the advantages such as being a part of the existing network, but locate their ateliers in different neighborhoods due to lack of space in Nisantasi (figure 5). Both showroom and atelier units need storage spaces. There is an optional design space connected with the showroom. The design unit in the atelier is compulsory space as design is an ongoing phenomenon at every moment of production.

3- Integrated Fashion Design Office Outside of Nisantasi

Figure 6: Scheme 3 - Fashion Design Office That Has Showroom and Atelier outside of Nisantasi

Scheme 3 includes all of the design and production spaces. Most of the designers interviewed imagine an office which has a showroom and an atelier where they can perform all production stages (Figure 6). The schemes can be applied in single-storey and multi-storey buildings.

In this scheme, the design unit is positioned to serve both the showroom and the atelier. All of the design and production stages work together. The designer is involved in production, produces ideas in the design process, uses his creativity until the end of the product, and takes part in every step of the creation.

Conclusion

Since the last quarter of 20th century, the concepts such as creativity, innovation and creative industry have begun to stand out. The creative class needs special working places. However, the studies on the working place of the creative class are very limited.

In this study, the working place of fashion designers are examined. In the study, working offices of the fashion designers are analyzed and evaluated in the urban and building scale. Firstly, the criteria

of location choice of the design offices are discussed. Then, by examining the existing offices, needs and desires of fashion designers, it is aimed to reveal the design criteria of the working place for them. For this purpose, fashion designers in Nisantasi, the district where fashion designers have located mostly, were interviewed.

According to Florida, 3T (technology, talent and tolerance) is effective in the location choice of the creative class. It can be said that Nisantasi has all 3T for fashion designers. Istanbul, the gateway of Turkey to the world, offers many opportunities for the creative class in terms of technology, a tolerant environment where people with different lifestyles live together, a space where people demonstrate their talent. On the other hand, the concepts of individuality, openness and difference, which are the values of the creative class, are influential in the location choice of designers in Nisantasi as well as in the design of their offices. These designers prefer work individually in order to design freely. The office conditions and working hours are flexible. They have the freedom to do their work, especially their design wherever and whenever they want. Most of the designs have a story and their inspiration is different. Designers have reflected these differences in their working space. Nisantasi also provide some other advantages attracting the designers to this district. Numerous accessory suppliers and fabric suppliers located in the district. Moreover, Nisantasi is a district where upper income people, who are the potential customers of the sector, live. All these factors have caused fashion designers to cluster in Nisantasi. In addition, being a part of the network formed by the designers in Nisantasi and providing information through this network is an important reason for the designers to cluster in the district. For the designers, having place in this network is important not only for information sharing but also being visible in the sector.

These factors related to the city have been influential in the location choice and clustering of fashion designers in Nisantasi. However, Nisantasi is a built-up neighborhood and the buildings are relatively old. Designer offices are often located in these old buildings. For this reason, designers work in physically unsuitable conditions. The spaces in the offices are insufficient and the connections between the spaces are weak. Ateliers and storage areas are insufficient in their offices, and even some designers carry out their production activities in ateliers outside of Nisantasi. Despite high rents, designers prefer to work in these offices with physical disabilities. This shows that, for the designers here, the location of the offices is more important than the interior features.

In the research, design and production have been seen as two basic intertwined activities in the design process. Designers usually make their designs outside the office and do not use a space for design in the office. This is due to the fact that the design process is independent of time and space. However, all designers emphasize that it is important to have an atelier in the office. Because the designer improves the design during the production process and changes when necessary. Another important venue in the offices is the showroom. In these showrooms, they both exhibit their products, make meetings, and sometimes use them for design. Designers dream of integrated workplaces with a large atelier, showroom and adequate storage areas, where all functions are combined. According to them, the fact that all the spaces are together is very important for the efficiency of the design process.

Urban design for multilevel planning

An inclusive, multilevel planning experience to regenerate Milan metropolitan peripheries

Nausicaa Pezzoni

Città metropolitana di Milano, n.pezzoni@cittametropolitana.milano.it

Abstract: “Metropolitan welfare and urban regeneration” is the project that the Metropolitan City Authority of Milan is carrying out thanks to a National fund by the Infrastructure Ministry of the Central State aiming at developing deprived areas in the country. The topic of inclusiveness is the key chosen by the Metropolitan City of Milan to interpret the issue of peripheries and the idea of urban regeneration. Its target is to transform marginal places into the pivots of a territorial and social infrastructure to build a new livability of the metropolitan suburbs, through a multilevel planning tool that involves the environmental level, such as the housing inclusion and the cultural and social promotion levels. It is mainly addressing the vulnerable population, and at the same time it aims at the construction of nodes of attractions for all the citizens. The paper presents the innovative approach of governance proposed by a program that experiments new relationships at the metropolitan scale, and the contents of the six different projects that compose the program interpreting the issue of integration as a fundamental criterion into planning tools aimed at responding to the current challenges.

Keywords: urban regeneration; welfare; metropolitan scale; peripheries.

Introduction

In 2016 the Metropolitan City of Milan participated to a national call for proposals for financing by the Infrastructure Ministry of the Central State (called ‘Bando Periferie’), aiming at developing deprived areas over the country. With the project “Metropolitan Welfare and Urban Regeneration. Overcoming emergencies and building new spaces of cohesion and hospitality”, the Metropolitan City of Milan has proposed to build a system of services and spaces for hospitality and social cohesion promoted and managed by a network of Municipalities that have identified places to allocate activities capable of taking care of the marginal context on their territory. Abandoned or never inhabited places have been identified, in order to turn them into the pivots of a territorial and social infrastructure able to aggregate diversified activities and to unite different subjects for the construction of a new livability of metropolitan suburbs. Through the networking of spaces, of actors, of planning by a multiplicity of aggregate administrations, a design logic defined as “open network” was introduced: a collaborative design that allows both to overcome the emergency logic with which complex problems like that of hospitality are faced, and to change the scale in which the issue of redevelopment is usually approached.

1. Metropolitan welfare as a design strategy

With the participation in the extraordinary program for the redevelopment of the peripheral areas [‘Extraordinary program of intervention for urban redevelopment and the security in the suburbs of metropolitan cities and provincial capital municipalities’ (ex D.P.C.M. 25/05/2016)], the Metropolitan City of Milan has embarked on a path that has marked a discontinuity with respect to the ordinary government practice for two reasons. The first relates to the interpretation of the issue ‘peripheries’ and the very idea of redevelopment, which has been focused on the paradigm of social inclusion; the second reason for novelty concerns the governance model that the Metropolitan City of Milan has started building, giving impetus to a planning experience based on an ‘open network’ logic.

From the point of view of the interpretation of the peripheral issue, the call for proposal ‘Bando Periferie’ urged us to ask ourselves questions about which territories should be considered peripheral, that is, on how to identify urban contexts towards which to direct the project proposals. In recent urban studies, the periphery has been described in different geo-political contexts and with different disciplinary approaches: it has been analyzed as dichotomous dependence of power on centrality (Kühn, Bernt, Colini, 2016), as a condition of spatial marginality and peripheralization (Naumann, Fischer-Tahir, 2013), as a socio-economic process of construction of the exclusion – ‘the making of marginality’ (Wacquant, 2015; Wacquant, Slater, Pereira, 2014), as a territory subject to financial predation strategies and a territory of conquest for urban growth (Bernt, Colini, Foerste, 2017). At the same time, public policies have turned their interest in the periphery within the framework of EU social cohesion policies, while central governments and local authorities have addressed it through national redevelopment programs (Soziale Stadt DE, Politique de la Ville FR, NDC in UK, Urbana ES, Bando Periferie Italia). On the basis of these analytical frameworks, it was highlighted how the theoretical analysis of urban disciplines has failed to effectively inform public policies and, vice versa, urban policies up to now interpreted only partially the theoretical-critical contribution. With the aim of starting to fill this gap, the Metropolitan City of Milan has built a project that focuses attention not only primarily on space, but on the social and economic processes that produce inequality.

The starting point was therefore to take periphery as a transversal issue to the different territories, identifying peripheral places as marginal due to social conditions, economic, cultural aspects of its inhabitants - even where these spaces were located geographically in a central area. The contents of the project derive directly from this definition of what can be considered periphery. Expanding the geographical horizon of what is peripheral has led to accepting the challenge of considering the whole Metropolitan area as peripheral; extending the semantic field means constructing a project for the redevelopment of the suburbs involving the different levels with which a program of urban redevelopment is called to measure itself: environmental and sustainable mobility on the territory, housing inclusion, social promotion.

Overall, the objective of the 'Metropolitan Welfare and Urban Regeneration' (MWUR) program is to trigger processes of redevelopment of spaces underutilized or abandoned through projects capable of responding to the housing demand of weak population and at the same time to the need for places for cultural and social activities aimed at supporting social inclusion: places open to the territory, spaces for welcoming and, at the same time, potential attractors for all metropolitan citizens, with functions of supra-municipal relevance. In particular, Metropolitan City has asked the Municipalities to develop projects that, declined in the context of living spaces rather than within the framework of an infrastructure upgrade, could combine within the same intervention the residential destination, or the public transport, with cultural or social service: integrated projects, suitable for diversifying the residential offer in relation to the specific needs of different types of inhabitants, or to identify actions to support living even independently of direct interventions on built environment.

2. A network logic for urban regeneration

From the point of view of the proposed governance model, the Metropolitan City of Milan has interpreted the participation to the extraordinary program for the redevelopment of the peripheral areas as an opportunity to transversally measure oneself with the fundamental questions of the metropolitan government and as an opportunity to define its own directing role with respect to themes and territories interested by the project. This planning orientation has been developed through promoting interdisciplinary work within the administration and initiating a practice of cooperation between different administrations and subjects involved in the projects. This perspective has been identified with the image of an 'open network': a strategic vision that responds to a logic of collaboration amongst groups of activities and subjects (not only institutions, but also associations, cooperatives, organizations) and which prefigures a progressive implementation of intervention programs.

In interpreting its directing role with respect to the planned territories, Metropolitan City proposed to the Municipalities to follow this logic, both through the consolidation of relationships between Municipalities that had already started shared projects on their territories, and through the activation of new networks able to work on strategic supra-municipal goals. Milan metropolitan territory is articulated in homogeneous areas - by geographical features, demographic, historical, economic and institutional - by the Strategic Plan approved with Council resolution of 12/05/2016 in order to aggregate decentralized metropolitan activities and services. This articulation constitutes a first, albeit embryonic, identification of 'territorial figures' (Gabellini, 2008, Pasqui, 2000), a reticular system aimed at promoting integration between similar services of single or associated Municipalities.

Following an open network logic meant triggering processes of urban regeneration within a collaborative design involving a plurality of actors, through the sharing of spaces and of planning by many aggregate administrations; it meant giving life to projects that involve repercussions, in terms of improvement urban quality, on different interrelated territorial contexts; it meant finally to put oneself in a perspective which provides for the replicability of virtuous models even on larger territories. The MWUR project is part of this vision. The proposal for a metropolitan welfare for urban regeneration is to build a system of services for welcoming and social cohesion promoted and managed by a network of Municipalities that have identified on their territory places to allocate these activities. Interventions for sustainable mobility, housing facilities, cultural nodes and programs for social inclusion are interconnected so that each Administration can draw, from the mutual relations that the different subjects involved will build, an advantage in terms of function, attractiveness and cost-effectiveness and therefore also in terms of a planning that can further develop and aggregate other projects giving rise to new territorial polarities.

3. An integrated program for a new habitability

Combining the residential destination with the cultural and social one within the same project, and diversifying the residential offer based on the specific needs of different types of inhabitants, mean designing places open to the territory: not just spaces for welcoming but also potential attractors for all metropolitan citizens, with functions of beyond-local relevance. The expected results of these processes involve several levels with which an urban redevelopment program is called to measure itself in the environmental and sustainable mobility level, the housing inclusion and the cultural and social promotion level.

From the urban environment point of view in which buildings or abandoned areas are inserted, an intervention of renovation focused on an inhabiting perspective that contains a wide spectrum of functions in addition to residence, will allow to transform marginal places – marginal because they are degraded or because they are excluded from privileged trajectories by the inhabitants –, in places of urban quality that can gradually become spaces of reference for social life of the territory. This transformation process is closely linked to accessibility through the existing public transport network and through forecasting or strengthening of a sustainable mobility system that can connect spaces and services not necessarily adjacent.

From the residential function point of view to which buildings will be mainly be used, the project responds to some of the most unresolved socio-economic emergencies of current events. Among them, the living of migrants, providing spaces for families or single people within a path of social integration; the cohabitation between different types of inhabitants, inserting accommodations for students, whose presence guarantees a continuous exchange between different cultures in addition to recalling activities able to revitalize the territorial context; the inclusion of vulnerable population, with the provision of rooms for the residence but also for a series of shared services, together with the identification of the most suitable forms of management.

Finally, from social promotion point of view, the redevelopment of abandoned places for living not separated from the creation of new public spaces, as well as the provision of services for integration and job opportunities (with refurbishing programs that include, for example, self-construction as a tool

for both economic advantage and professional training), will allow those who will live there to feel involved in a renewal project extended to several aspects of civil life. Also, it will help them, in general, to perceive the areas no longer as marginal places but as pins of a territorial and social infrastructure able to aggregate diversified activities and to unite different subjects for the construction of a new habitability of the metropolitan suburbs.

Six groups of Municipalities, which include a total of 31 administrations, have participated in the call for proposal, each interpreting the Metropolitan City's proposal on the basis of emerging problems and potentialities present in its own territorial context, in the perspective of triggering urban regeneration processes.

3.1 Urban and territorial redevelopment of the areas of M2 stations along the Martesana canal

Promoted by 7 Municipalities (Bussero, Cernusco sul Naviglio, Cassina de' Pecchi, Gorgonzola, Gessate, Vimodrone, Milan), the project involves restructuring and functional redevelopment of some stations of the M2 underground line and of the relative system of accessibility, which is accompanied by the recovery of social housing buildings and the redevelopment of a garden (Giardino Tre Fontanili) and of a bicycle path in the Municipality of Vimodrone and the realization of a bicycle workshop in the Municipality of Bussero. This project responds primarily to the goal of the Strategic Plan to "contribute to the development of infrastructure networks for mobility", included in the framework of a wider regeneration of the urban areas along the M2 line, through the recovery of buildings and public spaces and the activation of services that can give impetus to the entire territorial system along the Martesana canal (figure 1).

Figure 1: Urban and territorial redevelopment of the areas of M2 stations along the Martesana canal

3.2 Peripheries at the Center: redevelopment of the Pioltello Satellite district

The project involves the redevelopment of one of the areas most affected by marginalization processes in the entire metropolitan territory. Through a series of actions aimed at promoting social integration, a support policies for work, to enrich the offer of spaces and programs for recreational activities, the ‘Peripheries at the Center’ project aims to provide the Pioltello area, starting from refurbishment of a sports center and the opening of a housing support desk, by appropriate infrastructure for the inclusion of this geographical context in a broad system of multilevel relations that transform the condition of isolation in a condition of high urbanity.

3.3 Integration Machine

Starting from the redevelopment of three buildings in the Municipalities of Legnano, Rescaldina and Castano Primo, the project triggers a process of social inclusion that supports the creation of low-cost living spaces and related management plans, the participatory planning of some public places, the creation of new aggregation spaces, as well as job training for the young people. The project aims to consolidate an already existing collaboration between administrations and the third sector and to expand the network of actors involved also through participation processes, responding to the objective of the Strategic Plan to “implement policies aimed at sustainable social development and inclusive, guaranteeing all citizens equal opportunities”. The different nodes of this “integration machine” are networked not only through an integrated management system, but also geographically through the implementation of a local public transport line and the construction of a cycle path between the buildings to be redeveloped (figure 2).

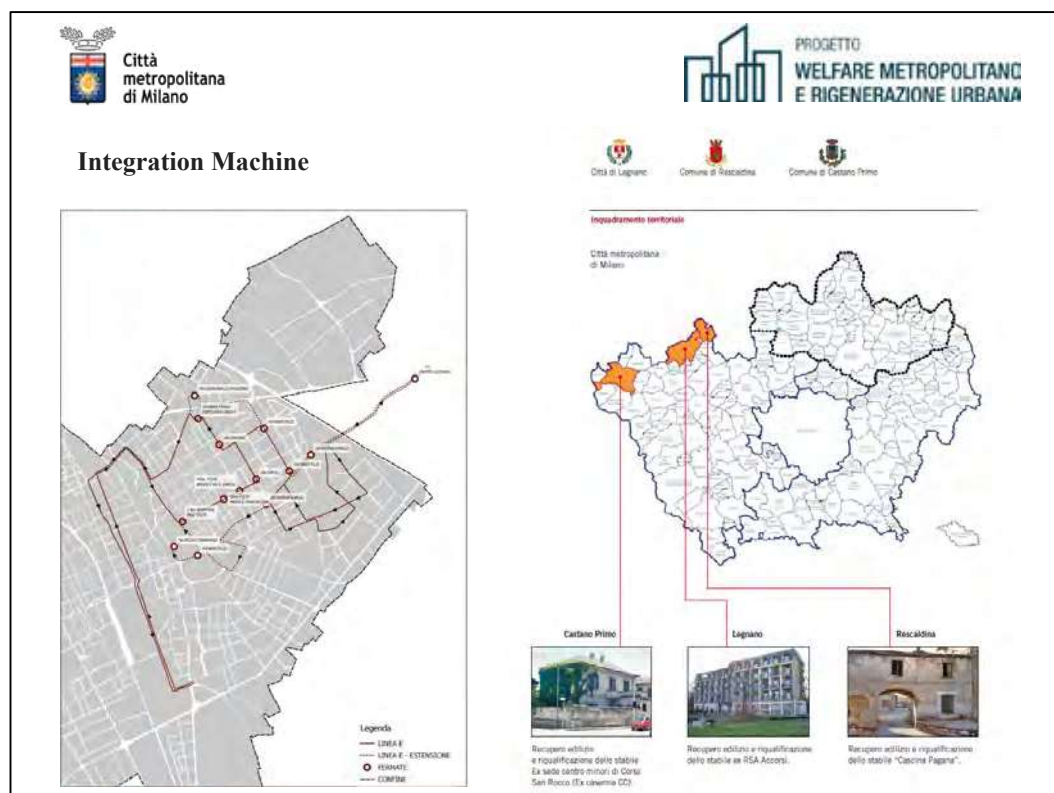

Figure 2: Integration Machine. Redevelopment of peripheries in the Northern part of the metropolitan territory

3.4 Urban regeneration in North Milan

The Municipalities of Cinisello Balsamo and Sesto San Giovanni present heterogeneous projects for the type of urban regeneration proposed, united by the intention of constructing a new identity of marginal contexts, because they are not easily accessible or they lack aggregation spaces of social and cultural services that distinguish them. There are two issues involved, the first of a predominantly social nature, the second marked by environmental requalification. The recovery and reuse of a historic farmhouse for a social housing intervention, the renovation of a school building, in addition to the creation of ‘Citizenship houses’ in which some of the projects related to the culture and sociality already present are put to system on the territory, are the projects aimed at promoting social inclusion. The creation of a cycling network of interchange between the Municipalities of Cinisello Balsamo, Milan, Sesto San Giovanni and Monza, and the project of a farmhouse and a rural park redevelopment, between the river system of the Lambro and the Parks of north-eastern Milan, instead propose to respectively enhance the nodes of interchange at the metropolitan scale, and to improve the landscape and environmental quality of what is today defined as a ‘no land use’ due to the presence, in particular, of a power line that is planned to be buried.

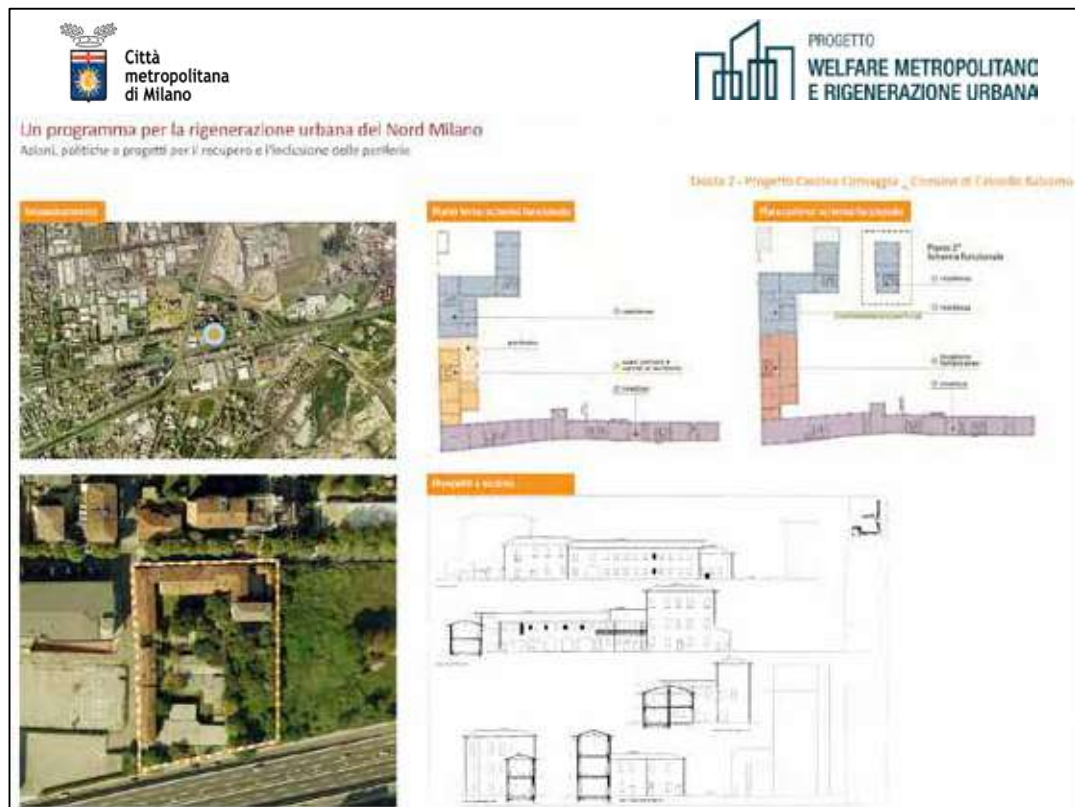

Figure 3: Urban regeneration in North Milan. The renovation of a farmhouse for social housing in Cinisello

3.5 RICA (Regenerating communities and living) towards Human Technopole

The project proposes interventions aimed at the social inclusion of various sectors of the population to generate new reference poles for the entire urban community. The recovery and re-functionalization of some buildings, including a road house owned by the metropolitan city, are designed to house elderly and an experimental didactic center for children, or an auditorium together with gathering places for the elderly and children, or the creation of a community hub and a space for living of weaker groups in the

same building. Regenerating peripheral spaces to integrate different functions related to living, through a project articulated in the territory of several Municipalities, answers the goal of the Strategic Plan to “promote, also through cooperation between the public and the public private, with particular reference to the third sector, a new generative welfare system, understood as a strategic lever for innovation”.

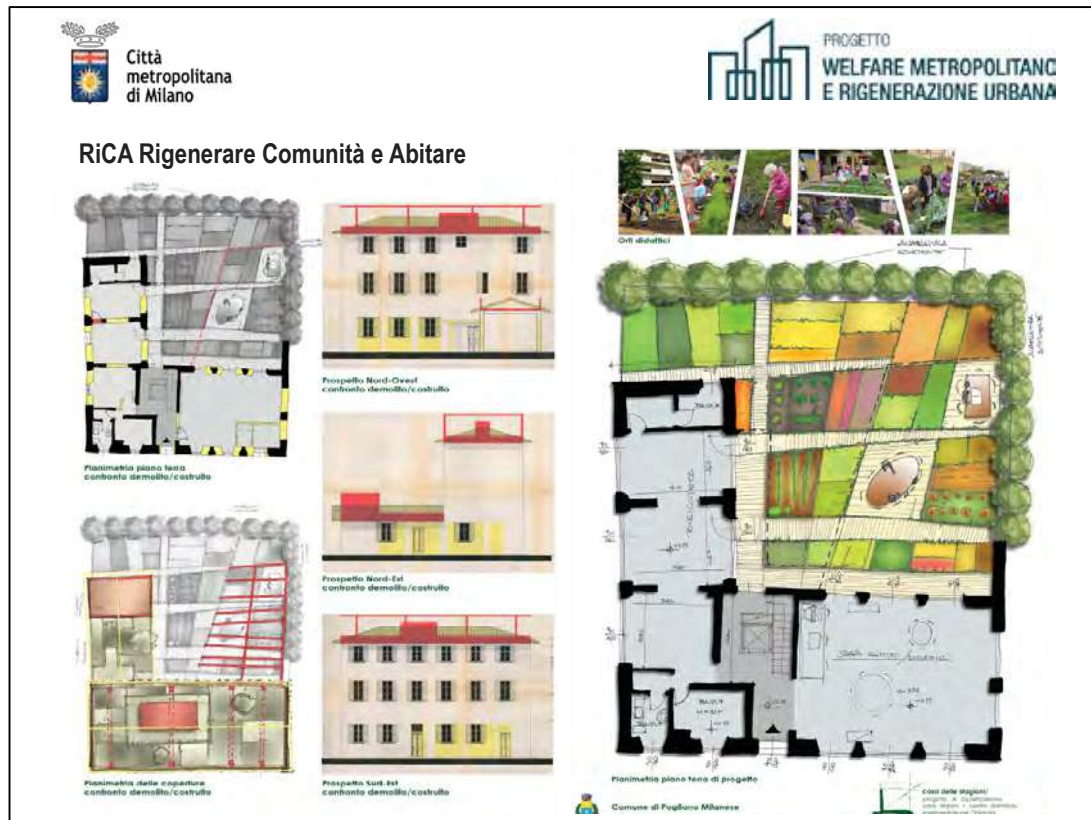

Figure 4: RiCA (Regenerating communities and living). The ‘Seasons House’ in Pogliano Milanese

3.6 For a city of us. Urban regeneration and socio-cultural development in the South West

In one of the most degraded socio-economic contexts of the Metropolitan City, the Municipalities of Pieve Emanuele and Rozzano propose to establish a stable organization in order to develop an inter-communal socio-cultural pole formed by three urban laboratories, redeveloping three existing public structures into one with a prevailing social characteristic, the other sportive, the last cultural. The project makes use of the consolidated collaboration between the two Municipalities to build a political, technical and associational coordination that promotes urban regeneration through measures to combat discomfort. The three laboratories are three incubators oriented towards promoting active citizenship and spreading social responsibility in city community, places of aggregation able to attract the talents and resources present on territory in order to build a neighborhood identity and to foster social relationships, responding to degradation problems related to high housing tension, a high rate of micro-crime and to the acute youthful unease that historically characterized this urban region.

Conclusions

The MWUR project can be read as an experiment of multilevel planning, as it has tried to stress the interaction between different levels of territorial government (the metropolitan and the municipal levels) and to implement the connections already existing from the geographical, infrastructural, social points of view, but which have not been acquired in urban planning yet. It has in fact proposed an articulated system of material and immaterial actions, considering the different levels involved in an urban redevelopment program: the environmental and sustainable mobility level, the housing inclusion and the cultural and social promotion level. Moreover, the projects have been realized by different actors, institutions, associations and stakeholders on the metropolitan territory, with the common goal of making urban regeneration, together with social inclusion, the core of a work of total rethinking of the metropolitan peripheries.

In light of the experience gained with this planning approach and after the first year of management of the MWUR project, it is possible to propose some suggestions in the perspective of moving from extraordinary planning to a new cycle in the governance at the metropolitan scale. The first suggestion concerns the process of renewal within the Metropolitan City of Milan, triggered by the project as it was conceived, and that could now be consolidated in the perspective of disseminating in other metropolitan areas the same multilevel approach expressed by the 31 Municipalities involved. The proposed interventions are guided by a unified interpretation of the issue of periphery and respond to the hypothesis that social inclusion can shape urban regeneration and that the redevelopment of the territory in turn is generative of social inclusion (Botto and Pezzoni, 2018). Both from the point of view of the issue that guided the redevelopment of the suburbs, and from the point of view of the experimented working method, the project MWUR marked a discontinuity with respect to the ordinary planning processes, indicating a possible direction of work in the practices of territorial government at the metropolitan scale. The conception of a project that made social inclusion the pivot around which to design the development of Milan's suburbs means going beyond the boundaries of traditional territorial planning sectors to respond more properly to the overall goal of *taking care* of areas considered marginal. On the other hand, a care of the territory that took into account the contextual criticalities required to diversify the interventions, focusing attention from time to time on aspects directly related to the physical space rather than on the difficulties of living connected to a specific urban context. Material and immaterial actions, variously combined in order to respond to the specific needs of each territory, have therefore designed the field of urban regeneration that has been defined in a close correlation with the conditions of marginality expressed by the territories themselves, as they were represented by the municipal administrations that have taken the theme proposed by the Metropolitan City into their projects. At the same time, the different interpretations of welfare, advanced by the metropolitan peripheries to rethink themselves, have made a concept explicit to be implemented, that of 'metropolitan welfare', which is the result of the opportunities for social inclusion identified in the single areas and networked with those of other contexts: a concept that cannot be separated from the intrinsic planning of each Municipality that has activated itself in transposing the questions of the territory and in proposing solutions open to fruition on the metropolitan scale. Finally, the general suggestion in the perspective to start a new cycle of governance at the metropolitan scale, based on an ordinary multilevel planning, is to strengthen and spread an approach to the entire urban region aimed at identifying the transformative potential of single places or the possibility of overcoming specific marginal conditions through integrated interventions that are inscribed in the broader design of a metropolitan welfare capable of regenerating the territory.

Abstract: Healthy city refers to a whole which is organically developed by healthy people, healthy environment and healthy society. It can improve its environment, expand its resources, and enable the urban situation to support each other so as to maximize its potential (Trevor Hancoc and Len Duhl). Xi'an Muslim Residential Area was formed after the Tang Dynasty and lasted more than a thousand years. Muslim settlements in Xi'an take mosques as the center and form a spatial pattern of Residence Around Mosques, which is continuing the traditional scale of urban street public life in China, and becoming an important carrier of people's emotions, life and communication space. Xi'an Muslims have a tradition of doing business, which the front of the house serves as a shop and the back yard serves as a residence. Therefore, the commercial activities there often extend from the first floor of the house to the street, forming an important public living space. With the extension of commercial activity space, this kind of place gradually becomes a functional medium, which softens the rigid boundary between the building and the street, thus forming a flexible space. This flexible space forms the event carrier of historical memory or the space field under the stack of daily life, which emerges a sort of reaction to space actors makes Muslim settlements have unique social and spiritual cohesion. It strengthens the stacking effect of historical information in urban space, then it constitutes the cultural information field of human-space-place. Taking Xi'an Muslim Residential Area as a case study, this paper analyses the types, attributes, characteristics and elements of these flexible spaces by the methods of typology, investigation data and Mapping, aiming at exploring the design method of traditional urban street flexible space based on the concept of healthy city as well as the healthy settlements.

Keywords: Healthy settlements, Street space, Traditional yardstick, Flexible space,

Introduction

Healthy city refers to a whole which is organically developed by healthy people, healthy environment and healthy society. It can improve its environment, expand its resources, and enable the urban situation to support each other so as to maximize its potential. The social value of flexible space originates from the pluralistic and complex nature of local residents, living places and public spaces, and has multi-functional adaptability. It is often manifested in the effect of space occupation and activity fields in pedestrian blocks. Investigations show that the flexibility of this space promotes the spiritual cohesion of local residents' society, strengthens the degree of social harmony, and further promotes the community health trends.

Since the Tang Dynasty, Xi'an Muslim Residential Area has been formed. It lasted 1300 years. With mosque as the center, Xi'an Muslim Residential Area has formed a spatial pattern of "encircling the mosque while living". It has continued the traditional scale of public living space in urban streets of China and become an important carrier of people's emotions, life and communication space. The social value of flexible space in Muslim neighborhoods (hereinafter referred to as "Muslim Square") is fully embodied and typical. Through the analysis of flexible space types, the spatial attributes, characteristics and elements of traditional street and lane public space are revealed, and the sociological value of flexible space in traditional urban neighborhoods based on the concept of healthy city is explored.

1. Research object and its background

Muslim neighbourhoods are located in the west of the Bell Tower in the old urban area of Xi'an, the central city of Northwest China. They cover an area of about 1.1 square kilometres (Fig. 1), starting from Shehui Road in the east, Zaozi Lane in the west, Hongbu Street in the north and West Street in the south.

Figure. 1 Scope of study and location map

Photo Source: Self-drawn by the author

The formation of Muslim residential space can be roughly divided into three stages: 1st, From the end of Tang Dynasty to Yuan Dynasty, Muslim settlements were formed and developed. The ancestors of Muslim settlements were mostly foreign nationals and their descendants. The

influence of Islam penetrated into all aspects of the lives of the ancestors of Muslim neighbourhoods.2nd During the Ming and Qing Dynasties, the basic pattern of Muslim settlements and a large number of historical relics and monuments were formed in the Ming and Qing Dynasties, and the spatial pattern of "Seven Temples and Thirteen Squares" laid the framework for the development of Muslim settlements.3rd Since modern times, the number of Muslim residents has increased significantly, forming a large-scale community. The infiltration of foreign culture and social fashion weakens the religious role of Muslim settlements, but the social organization form of mosque-Muslim community is still the basis of all kinds of relations in Muslim settlements.

The historical area of Beiyuanmen is located in Ming City of Xi'an. Drum-tower in the South and Beiyuanmen in the north and included the part of Xiyang Street and Huajue Lane, covering an area of about 9 hectares. Muslims are the main inhabitants. The section includes one of the key cultural relics protection units in the whole country - Drum Tower, and two of the key cultural relics protection units in Shaanxi Province - Huajue Lane Mosque and Gaojia Courtyard.

Figure . 2 Analysis and Investigation on the Current Situation and Publicity in Beiyuanmen Area
Picture Source: Drawing Based on Investigation Data by Author

The Muslims in Xi'an take business as their tradition and take family as the unit to form the space form of front store and back house or the space form of bottom store and upper house. Therefore, business activities often extend from the first floor of the room to the street, forming an important living space. With the extension of commercial activity space, this kind of place acts as a functional medium, softening the rigid boundary between buildings and streets, and forming a flexible space with social value because it bears specific public social activities. This

kind of flexible space forms the event carrier of historical memory or the space field under the stack of daily life, which reacts on the spatial behavior subject, makes Muslim dwelling have unique social and spiritual cohesion force, strengthens the stacking effect of historical information in urban space, and constitutes the cultural information field of human-space-place.

2. Medium Properties of Flexible Space

Jan Gehl put forward the concept of "flexible boundary" in his book *Communication and Space*, which wrote: Flexible

boundary is a transitional area which is neither completely private nor completely public. They often act as a connecting link, making residents and activities more relaxed physically and psychologically when swinging in private and public space.(Jan Gehl, 2002) , Flexible space, as one side of public space and directly connected area of buildings, plays a role in softening the interface between buildings and streets, and is an important container for attracting people to stay and promoting street life. According to spatial attributes, flexible space can be divided into three types: open, semi-open and introverted. The historical area of Beiyuanmen has abundant business forms and various stores, forming a flexible space with diverse forms and unique features. Flexible Space can be divided into public activity space, Street shared space, green leisure space and so on according to its spatial function. Its space has the property of medium space, which is the medium space of behavior transition, psychological transition and emotional transition.

Type	Space Form	Road Section	Photo	Elements
Open type	Small square space			open space, characteristic sculpture
	Street green space			stone bench, parterre, sculpture
	Entrance space of scenic spots			caves, stone tablet, billboards
Semi open type	Outer court of Street Shop			canopy, fence, tables and chairs
	Pedestrian space			canopy, works display shelf

Type	Space Form	Road Section	Photo	Elements
	Street space			canopy, tables and chairs
	Outdo or space of shops			canopy, stool, bronze statue, console
Intro verte d type	Shop space			Canopy, Commodity cabinet
	Outdo or space of shops			Canopy, Outdoor Operator
	Sidewalk space			Canopy, Food stall

3. Space-time field properties of flexible space

3.1 Hierarchy of Spatial Communication

The public space of Beiyuanmen block has multi-level communication functions, including daily communication of local residents, anonymous communication of citizens and tourists, and multi-polar communication of socialization.

(1) Daily communication: normalized hierarchical, hierarchical, classified communication space, and frequency assurance of communication, which is one of the important characteristics of urban modernity.

(1) Anonymous Communication: Seeking first experience of communication and self-choice of communication

(3) Social intercourse: regional activities and contacts, beyond the needs of contacts across time, space and region, such as kinship, neighbourhood, geography and industry, to obtain more abundant communication information and the basic basis for self-decision-making.

3.2 Street and Lane Vitality Externalization

According to the survey, the current business types of Muslim settlements are mainly divided into four parts: Muslim food, jewelry and jade antique trade, flower-bird-fish-insect commodity business and trading. Among them, the operation of Muslim food is its leading industry. There are 223 shops in the survey area, gathering many well-known snacks in Muslim settlements, including 11 centuries-old shops, with a strong business atmosphere. Muslim catering and retail trade are the main types of business in the area. Details are as follows:

Commercial and retail trade: mainly distributed in Huajue Lane and Beiyuanmen accounting for 50.45% of the industry mix. In recent years, the market share has gradually expanded, mainly serving tourists. Retail is mainly Muslim food, such as Muslim salted beef and mutton, in addition to Shaanxi local products and various tourist souvenirs, which is related to the vigorous development of tourism in recent years.

Muslim catering industry: mainly distributed in Beiyuanman and Xiyang City, accounting for 31.08% . Special snacks include steamed beef and mutton, stir-fried, steamed beef and mutton, etc. It serves both residents and tourists, and is the main feature of Muslim settlements.

Non-Muslim catering industry: mainly distributed in Beiyuanman, accounting for 4.50%, mainly snacks and drinks, serving tourists, is driven by the development of tourism in Muslim settlements.

Leisure and entertainment and supporting services: mainly distributed in the Beiyuanmen, accounting for 6.76% and 7.21% respectively. The main types are hotels, cafes and supermarkets. It is also driven by the development of tourism in Muslim settlements.

At present, the internal management mode of the district is mainly family-style small workshops, with family as the main unit. Store area is generally small, about 30-300 square meters, there is no large number of commercial facilities and large commercial service outlets.

Street vitality is reflected in the following four points:

(1) Functional format: life leisure, tourism leisure, business leisure, leisure after work; Its

functional format adapts to the derivative functional format of living space, employment space and business space.

(2) Spatial vitality: the consistency of space nature, space order and place spirit.

(3) Social Vitality: Medium Communication Space Promotes the Quality of Communication and Enhances the Acquisition of Spiritual Value of Places

(4) Economic Vitality: The traditional business form with family as the unit, the historical accumulation and the brand effect of historical stacking constitute the industrial chain and market environment based on the spirit of space place.

Fig.4 The Schematic Diagram of Investigation Results of Industry States distribution in Investigation Section
Picture Source: Drawing Based on Investigation Data by Author

3.3 Self-management of Urban Behavior

Because of the historical and cultural value of Muslim neighborhoods, the historical-spatial field composed of community groups and space carriers produces effect, which constitutes the characteristics of self-management of urban behavior. It involves the following three aspects.

(1) Place management: Place management is divided into urban management and community self-management, in which urban management mainly focuses on health and safety, while community management makes the relationship between business and residence close and complex. Muslim neighbourhood has become an environmental theme, reflecting the cultural connotation and denotation of the community's space and cultural characteristics.

(2) Scene management: The historical accumulation of family as business unit constitutes its specific environment atmosphere, which makes the sense of environmental symbols, color, texture and environment scale have the matching characteristics of block pedestrian space, space function and its behavior, showing the order under chaotic phenomena.

(3) Behavior management: In the space dominated by catering and tourism commodities, the family-based business has the characteristics of diversified development and diversity. Self-management mechanism is the spatial logic and order of acquisition of spiritual value based on the adaptability of place theme and emotional pleasure.

4. Self-organization of Flexible Space

In Muslim neighbourhoods, the traditional living space of streets and alleys bears the local history and memory, so it has cultural inheritance. However, the family-based business model also shows the trend of self-renewal and the gradual alienation of traditional business groups. However, in the process of self-development of stability and renewal, the interaction of various factors strengthens the complexity of the community and highlights its cultural, social and economic value, which is embodied in the following four aspects of the relationship and role process.

(1) Leisure life network: From environmental quality to communication quality, leisure life has obvious locality based on a daily life scene with historical atmosphere, and the multiple characteristics of spatial attributes endow the people in this region with greater tolerance for foreign cultural or fashion trends. Therefore, multi-cultural attributes and local living places pass through neighborhood formats. It generates the power of self-renewal.

(2) Derivation of public function: Communication center transforms from organizational behavior to leisure life behavior, which has prominent local characteristics, self-adjustment based on the complex functions of historical environment and public living space, and

infiltration and integration of daily life behavior and urban public life behavior. Strong regional characteristics have become an attracting factor of local life experience willingness. Public life functions derive and diversify around residential life functions.

(3) Multidimensional public life: Local micro-economic location factors make community life tend to be multi-centered and decentralized, while mosques play a composite role of economic, social and cultural effects of commercial integrity under cultural constraints. The function of public life is multi-dimensional and multi-level symbiosis and coordination, and it also meets the public and tourists'recreational life, business contacts and other public life behavior.

(4) Business form self-renewal: Starting from the traditional life form, it adapts to people's attention and pursuit of history and memory. As a result, the leisure life form in this area not only improves the economic benefits, but also promotes the communication activities of consumers. Through the adaptability upgrading of business form, the whole block is full of vitality.

5. conclusion

Healthy city refers to a whole which is organically developed by healthy people, healthy environment and healthy society. It can improve its environment, expand its resources, and enable the urban situation to support each other so as to maximize its potential. The social value of flexible space originates from the pluralistic and complex nature of local residents, living places and public spaces. It has multi-functional adaptability, often manifested as the effect of space occupation and activity field in pedestrian blocks. Therefore, the community flexible space design guided by social value is a new trend of urban space planning and design under the concept of health.

Abstract: The economic crisis of the past decade has exacerbated existing vulnerability problems in Europe, particularly in the southern countries. These relate to unemployment, poverty, housing conditions, access to basic services or insecurity issues, among others, and have affected particular groups as migrant or the elderly. Although the increase in quality of life is a transversal goal to cohesion and urban policies, the effects of vulnerability have only recently begun to be documented in scientific research. Generally, comparative vulnerabilities' assessments are based on limited (often economic) indicators or, if they are more comprehensive, on a limited territorial scale. Thus, they don't perform holistic analysis at national scale, nor comprehensive regional/municipal comparisons. Consequently, this paper presents a multivariate diagnosis of vulnerabilities at national scale, considering an array of indicators of quality of life in various domains as housing, health, accessibility, education, security or employment. Each indicator was geo-referenced and represented at municipal level, leading to the creation of indexes of vulnerability for each theme. An overall index of vulnerability combining all parcels was then composed through advanced statistical analyses' techniques. More than displaying territorial differences, this approach allows discussing different geographical realities within Portugal, and provide outputs for supporting planning policies concerning integration, social cohesion, urban equity, and the development of urban systems.

Keywords: Territorial cohesion; vulnerability; multi-scalar planning; Portugal

Introduction

The economic crisis that has affected Europe in the last decade has been particularly harsh to Southern European countries (Bosco and Verney, 2012, Whitehead et al., 2014, Torres, 2009, Cairns et al., 2014, Carballo-Cruz, 2011). Existing vulnerability problems have been exacerbated, and today, even if the crisis has officially passed, they are still felt. With austerity policies in place, aimed at correcting rising fiscal and external imbalances, countries like Portugal witnessed cuts in welfare benefits, wages and pensions, and saw the increase of taxes. An immediate consequence was the slowdown of production, consumption and investment, and the rise of unemployment. With the reduction of the purchasing power, the bankruptcy of families and businesses, the increasing gap between income and consumption, and the deterioration of the social security system, poverty levels have increased and new types of poverty have emerged.

Although the number of people at risk of social exclusion has decreased in Europe (Eurostat, 2019), the crisis, political unrest or citizen dissatisfaction have led to the emergence or the increased visibility of social vulnerabilities (Ranci et al., 2014). They have also contributed to increasing spatial segregation, poverty concentration and social inequalities (Madanipour and Weck, 2015). For example, access to basic services and socio-economic benefits have declined, and so have housing conditions (Frazer and Marlier, 2011, CECODHAS, 2012), whereas some types of crime, such as sexual and domestic violence, have increased (APAV, 2017). This denotes how particularly vulnerable groups, such as the low qualified, immigrants, elderly or youngsters, have been severely affected, leading to a social crisis as a result of the economic crisis. In countries where welfare support relies extensively on family resources – notably in southern Europe – these effects have created heavy strains (Madanipour and Weck, 2015). Consequently, in the words of Méndez et al. (2015) this not only brought about a second recession of the economy and a later phase of stagnation, but also emphasized the unfair distribution of its impacts.

Today, the most important political and planning discourses are concerned with responding to the UN's Sustainable Development Goals. These call, among other concerns, for the reduction of inequalities (Goal 10), and making human settlements more inclusive, resilient and sustainable (Goal 11). Quality of life (OECD, 2017), cohesion agendas (EC, 2017) and overall political initiatives (Madanipour and Weck, 2015) support such calls, advocating for policies to combat social inequality and exclusion, and emphasizing the importance of place-based approaches. However, if the scope of vulnerability issues, and their relation to sustainable planning, is being increasingly debated (Lee, 2014), the spatial dimension of social exclusion, poverty and overall vulnerability has so far been mostly neglected (Madanipour and Weck, 2015).

Impacts are not spatially uniform and the drivers for these patterns differ within countries and within regions (Marcinićzak et al., 2015). The spatial dimension of exclusion, for example, is visible in the patterns of spatial segregation, in small-scale concentration of urban disadvantage, or in the rural problems of remoteness and accessibility (Murie and Musterd, 2004). However, comparative assessments of vulnerabilities have so far strongly relied on economic indicators or, if they have a greater scope, on selected sectoral indicators or a limited territorial scale. Thus, they don't perform holistic analysis at national scale, nor comprehensive regional/municipal comparisons taking into account an extensive battery of indicators.

In Portugal, the most important strategic planning document, the National Plan for Territorial Planning Policies (PNPOT), has been revised in 2018. It aims, according to Resolution n.º 44/2016 of the Council of Ministers, to further promote the territorial dimension of the public policies at various scales, by reinforcing the contribute of the urban structure and the improvement of quality of life in the country's development. It also intends to promote territorial cohesion and economic development with a strategy focused on the development of jobs and wealth outside the major metropolis, thus potentiating endogenous resources and a more planned and balanced distribution of facilities, functions and services. These goals point towards the development of mechanisms to regulate territorial inequalities that include multilevel integration of actors and instruments, but also to the construction of qualitative and analytical diagnosis. It is expected that these mechanisms allow exploring the relationships between geographies of vulnerability and the spatialization of planning policies, hence supporting spatially selective interventions and place-based prevention strategies.

Using Portugal as a test-case and contextualized in the aftermath of the revision of PNPOT, the main goal of this research is to perform a multivariate, territorial-based diagnosis of vulnerability, by creating and developing an innovative vulnerability index. This index is based on a wide range of relevant indicators of quality of life in 9 different domains, ranging from housing to economy to health. The purpose is dual; first to overcome the lack of space-based assessments of vulnerability at national scale. Second, to provide evidence-base for reshaping policy approaches and developing integrated responses.

This paper is organized into five sections. The second section reviews the (European) literature in terms of the measuring of territorial vulnerabilities and spatial inequalities at national and sub-national levels. The third section explains the methodology. The fourth section discusses the results, displaying the composite indexes produced. The fifth and last section presents the conclusions. Different geographical realities of Portugal are pointed out, raising awareness to vulnerability issues and leading to discussions regarding social cohesion and urban equity, crucial within current territorial planning in the European context.

Measuring territorial vulnerability and spatial inequalities

Sen (1976) started her well-known 1976 paper on measuring poverty by stating that two distinct problems should be faced: (i) identifying the poor among the total population, and (ii) constructing an index of poverty using the available information on the poor. This simple statement is still extremely profound and extremely relevant today, even if we substitute the word “poor” for “vulnerable” or “excluded” persons, or other related concepts. There is still the need – even more so after an economic crisis – to understand the dimensions of vulnerability, as well as to construct territorial indexes that may help us measure, understand and overcome them.

As Brown et al. (2017) state, vulnerability has many facets. The term has been widely used, particularly on the last two decades, in several areas of knowledge from medicine, to criminology to risk management (Gallardo, 2018). It has become a keyword for addressing issues of inequality or adversity, related to aspects such as economic or social disadvantage, insecurity or limited coping capacity (Brown et al., 2017). The concept itself is multidimensional, entailing a conceptual diversity that relates to the material and moral fragility of the most marginalized individuals or groups in society. Sapountzaki and Chalkias (2014) describe it as the loss potential of human, social, and economic capital. For Gallardo (2018) it is a state of defencelessness against adverse shock that could inflict damage, characterized either by the presence of certain weaknesses or internal conditions (which determine the state of defencelessness), or by the presence of certain probable external shocks (for which there is no ability to cope). Simply put, families and persons have more difficulty in facing adversities and access universal benefits and rights, either because of lack of material resources such as income, education, precarious housing or health condition; or because of discrimination due to age, gender, geographical location or an unsuitable distribution of services or goods (Marques et al., 2016, Sen, 2003).

Notwithstanding, no consensus exists on how to identify and characterize vulnerable persons in a given society. The multidimensional character of vulnerability, exclusion, poverty or, on the opposite end, well-being, is difficult to grasp, measure or monitor (Madanipour and Weck, 2015). “We can never directly observe a household’s current vulnerability level”, wrote Chaudhuri et al. (2002). Indeed, it seems rather impossible to encompass it into a single variable or indicator, as it derives from the cumulative overlapping of various dimensions. Many recent assessments of vulnerability, particularly those associated to the recent economic crisis in Europe, focus mainly on single macroeconomic indicators related to employment (or unemployment) and income (such as the GDP) (Artelaris, 2017, Mohseni-Cheraghlo, 2016, Madanipour and Weck, 2015). However, the fluctuations in macroeconomic indicators have often been shown to not be significantly correlated with the changes of social indicators (Boarini et al., 2006). Nor are they considered to be enough to explain the dimensions of vulnerability in a crisis period, as they provide only a partial picture of living conditions, social progress and interactions, the human and social costs of recession, as well as of other elements such as health and safety (Artelaris, 2017, Decancq and Schokkaert, 2016).

Consequently, the focus on using solely economic indicators has been challenged, leading to the rise of multidimensional approaches (Di Berardino et al., 2016) and the development of composite indicators (Artelaris, 2017). Such indicators are naturally of great interest to local, regional and even national policies, as

they can condense information, and be more easily read and understood by stakeholders and decision-makers, facilitating policy evaluation and comparison (Dialga and Thi Hang Giang, 2017). However, the formulation of such indicators has been effectively restricted. A critical aspect is the selection of the components themselves (OECD, 2008, Decancq and Schokkaert, 2016), more than often conditioned by the availability of statistical data, which results in the use of only a small number of variables (Artelaris, 2017, Madanipour and Weck, 2015). Furthermore, it is necessary to select the weights attached to each dimension, something that has been an object of extensive debate in the literature (Lee, 2014). Not prioritizing variables may cause deviation from reality; whereas weighting can produce distortive results. Variation in units of the indicators and their different directions may also cause problems. Lastly, another present critique is that the spatial dimension of exclusion or vulnerability has been mostly neglected (Madanipour and Weck, 2015), resulting on a little territorial decomposition of the results (Artelaris, 2017, Madanipour and Weck, 2015).

The theoretical framework suggested by the OECD (2017) in their ‘How’s Life’ series relates to eleven dimensions; namely Income and wealth, Job and earnings, Housing, Work-life balance, Health status, Education and skills, Social connections, Civic engagement and governance, Environmental quality, Personal security and Subjective well-being. Previously, the European Statistical System (2011) had referred to most of the same dimensions, under slightly different names (see Decancq and Schokkaert (2016) for a comparison). Many authors have added other dimensions to cover relevant points, notably the social dimension. For example, Decancq and Schokkaert (2016) added control or dummy variables related to household size, gender, age or belonging to an ethnic minority. Artelaris (2017) added four additional dimensions related to social exclusion, social capital, family and demographic dynamics. Besides presenting similar domains as the previous, the ESPON project TiPSE - The Territorial Dimension of Poverty and Social Exclusion in Europe (ESPON, 2014) also allowed for variables related to Transport and Communication or Ethnic Composition.

Lee (2014) reviews several authors who have shown correlations between social vulnerability and indicators as various as Female population, Age, Population density, Birth rate, Infant mortality rate, Households with disabled members, Social and economic status, Poor population, Income, Percentage of population 25 years or older with lower than high school diploma, Rates of unemployment, Working population in primary sector, Strength of social network, Percentage of houses rented or seasonal houses, Public infrastructure and resources that belong to inhabitants, Quality and price of house, and Percentage of old house. The author himself, due to data collection constraints, uses just 13 indicators. Table 1 synthesizes the variables used by these and other authors including Sapountzaki and Chalkias (2014).

Table 1 – Variables for measuring vulnerability and well-being in the literature

Authors	Lee (2014)	Sapountzaki, Chalkias (2014)	TIPSE project (ESPON, 2014)	Decancq and Schokkaert (2016)	Artelaris (2017)
Measure of:	Social vulnerability	Social-human vulnerability	Social exclusion	Well-being	Social Well-being
Scale	Township	Metropolitan	Macro-region	Country	Region
OECD framework					
Income and wealth	% of low-income population	Human poverty	Disposable income	Total household income per capita	Disposable Income (per capita); At risk of poverty rate
Housing	Peasant household; fishing household; % of single-person households		Tenure status; Density; Amenities		
Education and skills	% of population aged 15 years or older with educational attainment below high school	Illiterate rate	Access to different kinds of school, college, cultural facility; Attainment (ISCED levels)		Early leavers from education and training (from 18 to 24 years)

Environmental quality	Superficial measure of cultivated land				
Health status	Average number of patients who were served by hospitals; Number of hospital beds per 1000 inhabitants	Old age index	Access to primary health; Healthy life expectancy	Self-reported health	Medical doctors (per 100,000 inhabitants)/ Infant mortality rates (per 1000 live births)
Job and earnings			Employed / Unemployed; Inactive; Long term unemployed; Jobless households	Unemployment status	Unemployment Rate (%)/Average number of usual weekly hours of work in main job; Long-term unemployment (%)
Work-life balance					
Social connections				Frequency of social meetings with friends, relatives or colleagues	Family Divorce rate (per capita)/ Number of marriages (per capita)
Subjective well-being			Dependency rates		Suicide rates (per 100,000 inhabitants)
Civic engagement and governance			Voters; Civic engagement; Membership of NGOs		% Voter turnout in national elections
Personal security			Crime rates	Feeling safe when walking alone in local area after dark	Homicide rates (per 100,000 inhabitants)/Burglary rates (per 100,000 inhabitants)
Other domains					
Population	% of females; % of Elderly; Population density; Crude birth rate; % of physically and mentally disabled	Population density	Ethnic composition; Proportion from minorities; Migrants as share of population	Household size, education, gender, age, marital status, being religious, urban, belonging to an ethnic minority	% Population Growth (%); Young people neither in employment nor in education and training
Transport and Communication			Post Office; Broadband; Public transport; Car availability		

Methodology

The first decision made by the project team has been to select the most important domains in order to perform the vulnerability analysis. Two methods have converged. First, an analysis of the literature review (see previous chapter). Second, a group of discussions with an expert stakeholder team. Striving for an integrated approach, complex yet easily understandable, towards measuring and representing social vulnerability in Portugal, the result has been the decision to consider nine different domains. These have been i) housing (problems and constraints of the market...); ii) employment (unemployment, precariousness, income, qualifications...); iii) education (lack of schooling, lack of performance, social contexts...); iv) health (untimely death, morbidity, offer of services...); v) services of social interest (offer, accessibility...); vi) income (inequalities, savings, power of purchase...); vii) safety (crime rates, crime typologies...); viii) environment (conditions, behaviors, offer of services...); ix) vulnerable groups (poverty, social exclusion, conditions for social vulnerability...).

Most of them have a direct relationship to the domains in Table 1. Others are a parcel of those domains (such as vulnerable groups for Population; and access to facilities for Transport and Communication). Variables directly related to work-life balance, social connections and civic engagement and governance have not been directly

considered, as they have not been in previous studies. This is mostly due to the absence of data. In view of these constraints for obtaining detailed and extensive data at municipal level for each domain, the project team has chosen to use exclusively open-access statistical information at municipal level. This included data made available by the Portuguese National Statistics Institute (INE, 2019); an Institute responsible for the production of official statistical information, collected and condensed from an array of multiple primary sources. Furthermore, the official websites of the Ministry of Education and the Ministry of Labor and Social Solidarity were consulted, where different types of information were condensed to build new indicators.

The project team had discussion with thematic experts in order to select, of the available indicators for each domain, which ones should be included in the vulnerability analysis. A difference to previous studies lies in the fact that a large array of variables has been selected within each domain, rather than just one or two representative variables. Furthermore, for each domain the analysis has been structured to respond to two main objectives. The first has been to evaluate the specific types of vulnerability that each domain contains. For example, housing problems (such as homes without bath, or in a bad state of conservation) in the housing domain; the levels of unemployment in the employment domain; or the poor accessibility to services of social interest in the accessibility domain. A total of around 10 such indicators have been selected for each of the 9 domains, totaling 83. The second objective has been to evaluate the context that may influence the levels of vulnerability in each domain. For example, the pressure of the housing market in the housing domain; the low salaries and the precarious job offers in the employment domain; or the low levels of power of purchase and savings in the income domain. A total of around 5 indicators has been selected by the team of experts for each domain, totaling 49.

Considering the 9 different domains, a total of 132 indicators were collected. For each indicator, the most recent available data was used, although this means that some indicators, such as overcrowded dwellings, were produced using data from 2011 (the last population census in Portugal and sometimes the only information source available for a given variable), whilst other indicators were produced with data from 2017 (such as average rent values, or buildings rehabilitated after 2011). In some cases, in order to add consistency to the analysis and eliminate the influence of less frequent events, an average of three consecutive years was produced. This has been done for example for crime rates (in the safety domain), where an average of values from 2015, 2016 and 2017 (the last three data years available) were used.

Using this criteria and ArcGIS software, each one of the indicators has been cartographed at national scale (see figures below). In each map the municipalities were divided into five classes, using natural breaks, ranging from low to high incidence of the given indicator. Such procedure allowed for the elimination of differences in scale between indicators when the overall vulnerability index was computed, thus putting the emphasis on comparable territorial differences. Consequently, another difference to previous studies has been not to use a mathematical formula to sum the different variables in order to produce a composite indicator, but rather to perform a Multiple Correspondence Analysis (MCA) for each domain. MCA, an extension of correspondence analysis (CA), is an exploratory data analysis technique that allows analyzing patterns of relationships of several categorical dependent variables. It can be regarded as a form of factor analysis for categorical data (Greenacre, 2017, Yelland, 2010, Abdi and Valentin, 2007) that, through the reduction of the dimensions of a given dataset, facilitates the analysis of the relationships therein. Partial indexes of vulnerability were thus produced for each indicator, and the results identifying the most vulnerable territories were discussed with territorial experts (for example of the Commission of Coordination).

From each partial index the most representative indicators (with the highest test-value) were selected, in order to feed an overall index of vulnerability combining all domains. These were the ones displaying greater significance in the territorial differentiation of vulnerabilities in each domain. About 70 of the original 132 indicators were selected for computing the composite index; around 40 for the identification of the territorial specificities of vulnerabilities (1st objective), and around 30 for the identification of the territorial contexts

affecting vulnerability (2nd objective). MCA was then performed, considering the first set of variables as active and the second set as passive. This resulted in an overall synthesis of territorial vulnerability.

Results

For this paper, and with the impossibility of showing all maps concerning the 130 indicators within the 9 domains, the housing domain has been selected as an example. Figure 1 shows the two final maps for the housing domain. The first map represents the synthesis of housing vulnerabilities in Portugal. It has been produced combining around 10 different indicators of housing problems, for example those related to derelict buildings, overcrowded dwellings, social housing dwellings, families to rehouse, among others. The second map represents the synthesis of the contextual vulnerabilities that may influence the housing domain; most notably the pressures on the housing market. Variables used to compose this second indicator include the average rent value, the bank evaluations by square meter of homes or the percentage of local accommodations.

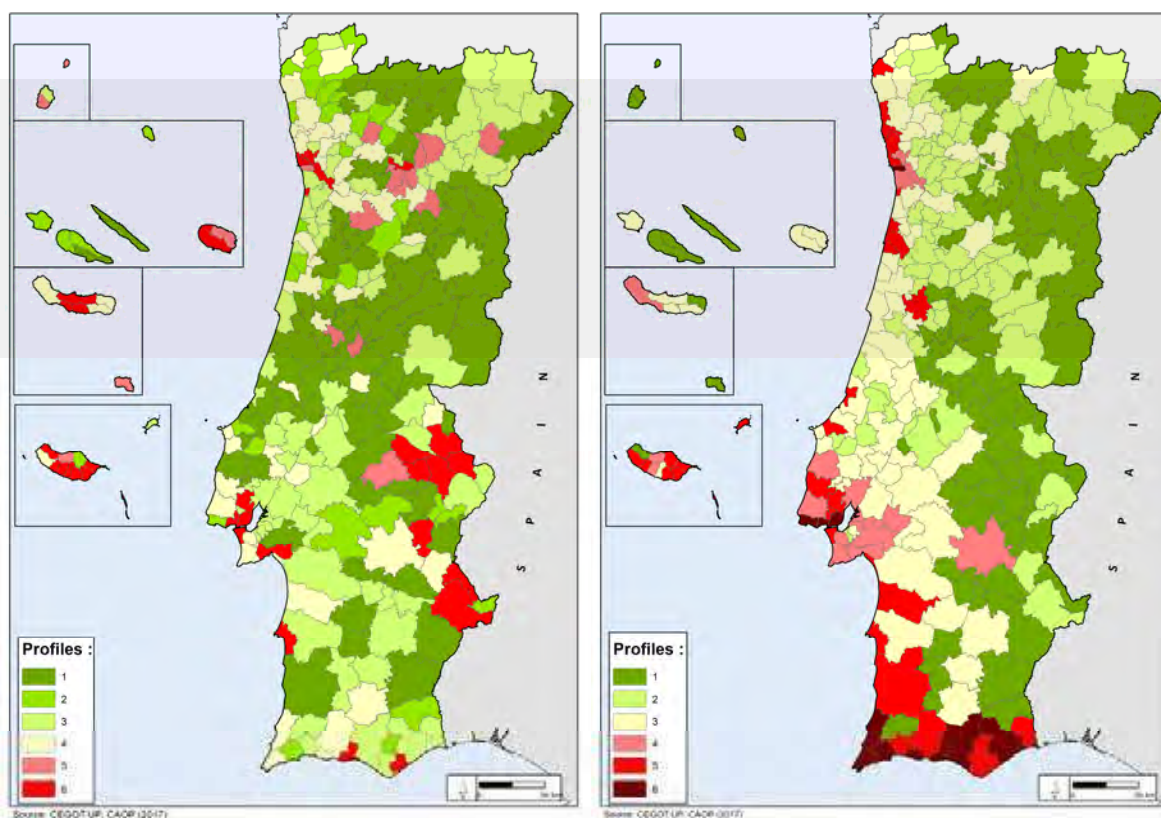

Figure 1 – (a) Synthesis of housing vulnerabilities; (b) synthesis of contextual vulnerabilities that may influence the housing domain

The highest profiles represent those where the amount of problems is larger. In territorial terms, it can be seen that housing problems (Figure 1a) feature more in the metropolitan areas of Lisbon and Porto, but also in some coastal areas, closer to the border with Spain and in some islands of the archipelago of Azores and Madeira. Although there is a strong presence of social housing, this profile is characterized by a large need of families to rehouse and overcrowded dwellings. It is also underlined by a large unemployment rate. Problems are also visible in Profile 5 in municipalities of the interior Portugal to the centre and the north, where there is a very high percentage of derelict buildings. The population in these areas is characterized by low incomes and not having an university education.

Nonetheless, the majority of Portugal has mostly been placed in Profiles 1 and 2. Both have in common a large number of derelict buildings and a medium to high population without an university education. Profile 1, dominant in central Portugal, is further distinguishable by low social housing but also low overcrowding and employment. Profile 3, with some predominance in the littoral, both to the north and the south, also shares low social housing and a medium amount of derelict buildings and families to rehouse, but is more characterized by very low incomes. Profile 4 is distinguishable by the amount of overcrowded dwellings.

The synthesis of contextual vulnerabilities (Figure 1b) clearly displays the differences between the interior and the littoral, and also between these and the areas around the metropolitan areas of Porto, Lisbon and the Algarve. Indeed, this is clearly the most problematic region, with profile 5 and 6 relating to high housing prices and rent values and large number of local accommodations. Profile 6 is also particularly characterized by unemployment and low incomes. Whereas the interior of Portugal is characterized by profiles 1 and 2 (low rents, low housing prices, low number of local accommodations), the littoral is characterized by profiles 3 and 4, where rent values and housing prices increase as the main cities of Lisbon and Porto are approached, and the percentage of income spent on housing is high.

Housing policies should be able to cross the two analyses, understanding that housing pressures are concentrated in Lisbon, Porto and the Algarve, but housing problems appear both in rural and urban territories. The most sensitive areas are those where bad housing conditions and a high pressure on the housing market, with elevated prices, hinder the access to a proper home.

Figure 2 represents the overall vulnerability results, considering all 9 domains and the 70 most representative indicators, resulting from the partial analyses, as the one for housing seen in the previous paragraphs. Five profiles have been identified, which display clear territorial patterns. Profile 4, for example, is clearly found in the interior north of the country. It represents an elderly, low income population, with poor school qualifications and a high degree of school abandonment, suffering from long term unemployment. Families are large, building dereliction is a problem and the access to high order services is low. On the other hand, Profile 5 is clearly seen around the major metropolitan areas of Porto, Lisbon and Faro (in the Algarve), as well as around other relevant medium-sized cities in the centre and south. It corresponds to a population highly qualified, with high power of purchase and high access to services, characterized by more than the average of single parent families and migrants. However, salaries are often low, the rent and evaluation values for homes are very high (although the number of social housing is also high), and there are greater problems with health, overcrowding and crime.

In between, Profile 1 is more prevalent in the littoral and center of the country, whereas Profile 3 is more prevalent in the interior, centre and south. Profile 1 has low levels of unemployment, overcrowding, housing rents, health problems and crime, and high levels of people with a complete basic education and high access to proximity services. However, incomes are low, and so is public employment and the number of social houses. Having large forest areas, these territories are also more susceptible to forest fires. Profile 3, on the other hand, is a territory susceptible to desertification. Although there is a high percentage of public employment, the percentage of elderly living alone and people with low education is high, and there are low levels of power of purchase and access to proximity and high order services. Housing is evaluated at lower values by banks and municipalities have high level of environmental expenses. Profile 2 has only a small expression in the outer rim of the larger metropolitan area of Porto. Is is distinguishable by very high levels of proximity to services, large families, single parent families and younger population. There are, however, low levels of public employment, long term unemployment and the weight of the housing rent in the family income is high.

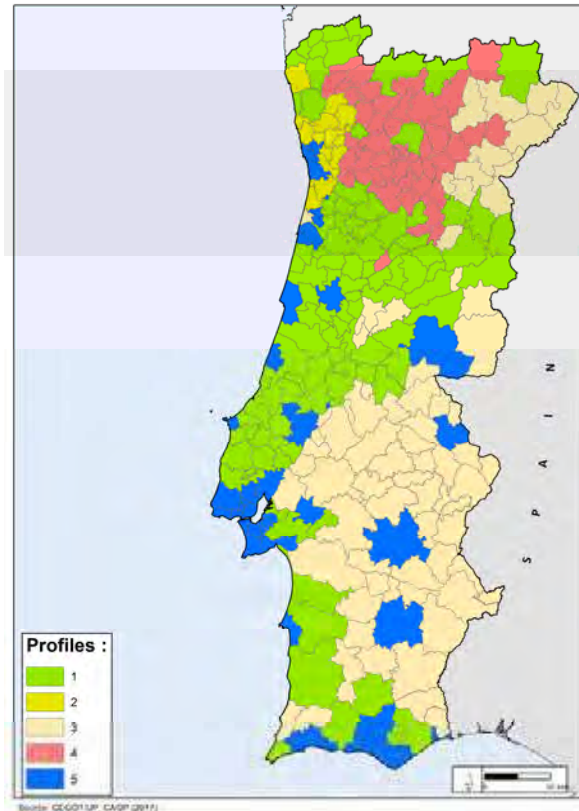

Figure 2 – Synthesis of overall vulnerability problems

Conclusions

As Lee (2014) argues, the traditional planning paradigm often stresses physical vulnerability and exposure to risk, with only a few studies applying social vulnerability to planning practices. However, in a post-crisis era, where social constraints are far from solved, the main planning agendas point towards the development of instruments capable of offering policy insights for promoting quality of life and spatially just and cohesive societies. This means improving several social indicators and reshaping how regional problems are approach (Artelaris, 2017). Combining both, it seems necessary to re-conceptualizing how territorial and social vulnerabilities as well as spatial inequalities are assessed, and how such knowledge can be integrated in strategic decision making.

In this paper, we have succinctly summarized an innovative approach applied in Portugal in the aftermath of the revision of the National Plan for Territorial Planning Policies (PNPOT) in 2018. The multivariate approach at national scale, using the municipality as a unit of measure, allowed for the extensive characterization and understanding of the territorial contexts of vulnerability and exclusion in Portugal. Firstly, it has to be acknowledged that this rather lengthy approach (over 130 indicators were initially analyzed and computed) is a step forward from previous works, because the complexity of the vulnerability phenomena, composed by a wide range of indicators of an economic, social and even physical nature, cannot be encompassed by single indicators. As Artelaris (2017) writes, wellbeing is inherently multidimensional. Even so, composite indicators themselves are the object of criticism (Dialga and Thi Hang Giang, 2017, OECD, 2008) because they may be misleading if poorly constructed and their construction often relies on subjective judgments. Yet again, i) by applying a methodology in stages, where each domain is analyzed individually and then only the most influencing variables are used for the final index score; ii) by dividing the variables in those directly related to

problems and those related to context; iii) and by using MCA rather than a mathematical expression, many of these criticisms can be overcome.

Besides displaying a national vision of vulnerabilities, replicable to other contexts, these results are intended to bring positive outputs for the guidance of planning policies regarding quality of life and the development of urban systems, by providing evidence-base for integrated responses.

GRENOBLE-ALPES AND THE ECOLOGICAL TRANSITION: TERRITORIAL PLANNING IN MOTION

Natacha Seigneuret

Architect and urban planner

*Head of the Federative Research Structure on Territories, Université Grenoble-Alpes
Researcher at the Centre for Research in Building Cultures (AE&CC)*

natacha.seigneuret@univ-grenoble-alpes.fr

Abstract: In this article we make the following hypothesis: sustainable urban development and climate change adaptation policies have had significant effects on the reconfiguration of territorial planning systems, and we analyse this evolution in the context of a European territory. Since the early 2000s, the Grenoble metropolitan area has carried out a series of actions (tram and bicycle path network, adopting a “Plan climat”) and launched related projects (“Ecoquartiers”, “EcoCité”), which explains why it is often considered a pioneering territory in terms of sustainable development and adaptation to climate change. The revamping of public policies to better meet the challenges of ecological transition explains the overall transformation of the planning system that has been in effect until now. Moreover, for “Grenoble-Alpes Métropole”, the recent change of status is a moment of change for the territorial planning strategies. The establishment of the metropolis and the obligation it has to quickly have a “Plan local d’urbanisme intercommunal” now allow it to build a strategy based on a common vision of the urban area and its development. That’s why this strategy leads to the search for a kind of multilevel territorial planning that is flexible, proactive and in motion.

Keywords: Ecological transition; Multilevel planning in motion; Urban demonstration projects; Grenoble-Alpes Métropole.

Introduction

Since the early 2000s, a series of actions have been launched in the Grenoble metropolitan area: developing a tram and bicycle path network, adopting a “Plan climat” and launched related projects: “Ecoquartiers, EcoCité”, which explains why “Grenoble-Alpes Métropole” is often considered a pioneering territory for sustainable development and adaptation to climate change. And more recently, in early 2019, Grenoble decided to take part in the competition rewarding Green Capitals.

The revamping of public policies (environment, mobility, urban planning) with the goal of better meeting the challenges of an ecological transition that lies ahead explains the comprehensive

transformation of the planning system that has been in effect until now. In a metropolitan context marked by institutional fragmentation, the planning process is incremental in nature, which shows why local actors favour specific projects over planning strategies. The change in status of the “Grenoble Alpes Métropole” in 2015 explains the emergence – on the scale of the metropolis and no longer of the municipalities – of new planning, based on the vision of a mountain metropolis organised in a polycentric manner. The establishment of the metropolis and the obligation it has to quickly have a “Plan local d’urbanisme intercommunal” now allow it to build a strategy based on a common vision of the urban area and its development. That’s why this strategy, which is developed in close collaboration with the municipalities, leads to the search for a kind of multilevel territorial planning that is flexible, proactive and in motion.

In this article we make the following hypothesis: sustainable urban development and climate change adaptation policies have had significant effects on the reconfiguration of territorial planning systems, and we analyse this evolution in the context of a European territory. First, after presenting our methodology, we will begin by analysing the consequences of ecological transition on territorial planning systems. Then, in second part, with the case of “Grenoble-Alpes Métropole”, we will present the context, the relationships between spatial planning and urban demonstration projects, the actors involved in the story of building a sustainable urban development strategy and, in third part, we will analyse the new modes of governance and Grenoble’s territorial planning in motion.

Part 1: Methodology and relations between ecological transition and territorial planning systems

1.1 A qualitative research methodology

This section draws on the results of research (POPSU¹, 2011-2018; CFE², 2016) conducted on strategies and projects implemented in Grenoble (France). In this research, we examined the issues of strategies, projects and governance. This work was done, on the one hand, by analysing documents on the national and regional energy policies and studying strategies of territorial planning and landmark urban projects at the local level and, on the other hand, by carrying out in situ investigations, conducting a series of interviews with elected officials, technicians, architects, urban planners, engineers, academics and residents and paying visits to architectural and urban operations. This approach enabled us to understand the drivers of urban ecosystem that foster the emergence of social and technological innovations in order to manage ecological transition at the local level.

The analysis of urban projects and strategies was conducted with a funnelling approach: from the current situation (political and administrative systems, energy policies and national players) to regional energy planning and policies to the specific context of territorial communities, local urban planning and landmark urban projects. The analysis may be close to what Yves Chalas calls a figurative analysis (Chalas, 2000), which is an approach that seeks to produce representations of an

¹ POPSU : Plateforme d’Observation des Projets et Stratégies Urbaines : Etude du cas de Grenoble_Alpes Métropole dans ce programme de recherche encadré en par le Ministère français de la Transition Ecologique et Solidaire.

² CFE : Conseil Français de l’Energie : programme de recherche sur l’Impact du développement de la Décentralisation des Energies sur le système Energétique

urban reality by giving equal weight to observation, description and analysis. The goal of this approach is to focus more on the relations than the oppositions that may exist between metropolitan planning strategies and the implementation of local urban projects.

In this way, we show how the proliferation of actors – and especially of the relationships that are cultivated – reveals a process of cooperation aimed at reducing technological uncertainty and increasing the stakeholders' innovation skills. The aims of Grenoble are entirely in line with the desire among local authorities to develop links with private economic actors and research organisations in order to enable the development of urban demonstration projects.

1.2 Sustainable development and the transformation of territorial planning systems

Because they lead to a pursuit of greater coordination between actions related to urban planning, the environment, mobility and energy management, policies for sustainable urban development and adaptation to climate change have had significant effects on the reconfiguration of territorial planning systems at the metropolitan level. In a world that continues to look uncertain, strategic and spatial planning, like its predecessor, strategic planning, as seen in Figure n°1, is both an exploration of transformation possibilities and an experimentation with solutions through the launching of projects, which are no longer necessarily large projects.

Figure n° 1: The main stages of French territorial planning

	Main objective	Approach	Method of elaboration	Modalities of stakeholder involvement	Implementation
Planning of land use	Management of urbanization and extensions	Comprehensive approach	Procedure conducted by the public power exercising hierarchical power	Consultation of civil society actors, once the objectives have been defined	Application of a regulation
Strategic planning	Economic development	Elaboration leading to a selection of <i>key issues</i>	Process constituting a strategic cycle in which milestones (goal development, implementation, evaluation) are equally important	<i>Collaborative planning</i> with stakeholder involvement throughout the process. Process that can lead to a pact of mutual commitments	Major projects, supposed to have a ripple effect on the development of the rest of the agglomeration
Strategic and spatial planning	Sustainable urban development	Production of a vision (<i>leitbild</i>).	Process - leads to several territorial scales, - involving a plurality of public and private actors, - mobilizing a variety of tools (territorial plan, sectoral plans, projects, guidelines and regulations)	<i>Collaborative planning</i> using innovative methods of involving civil society actors (shared diagnosis, workshops, forums ...)	Definition of network projects (mobility networks, network of centrality, green and blue weave) having a structuring effect of urbanization.

Source: Gilles Novarina and Natacha Seigneuret, 2018.

Using the metaphor of navigation proposed by Jean Hillier (2011), we can affirm that strategic approaches, whether plans or projects, must both set a course, which corresponds to defining the elements of a medium-term vision, and identify the stages, which corresponds to the projects that make it possible to translate this vision into actions. This desire to associate a distant vision with immediate action assumes, on the one hand, the linking of systems such as thematic groups, forums, public facilitating the involvement of the actors and, on the other hand, the use of new communication techniques such as exhibitions, digital collaborative cartographic platforms to mobilise the public (Balducci, 2011).

Because it calls for the alignment of sectorial policies for economic development, urban development, mobility and the environment, sustainable urban development requires that territories' material and physical organisation be taken into account. Thus, the promotion of sustainable mobility is easier with an organisation of centralities in coordination with the structure of the public transport network (train, metro, tram), the preservation of biodiversity is facilitated by the networking of natural spaces, and energy cogeneration plants operate better in compact spaces in city centres than in the territories of the diffuse city (Novarina, Seigneuret, 2019). Sustainable development policies remind their stakeholders of the importance of the constraints and the path dependency arising from the territorial structures they are trying to act on.

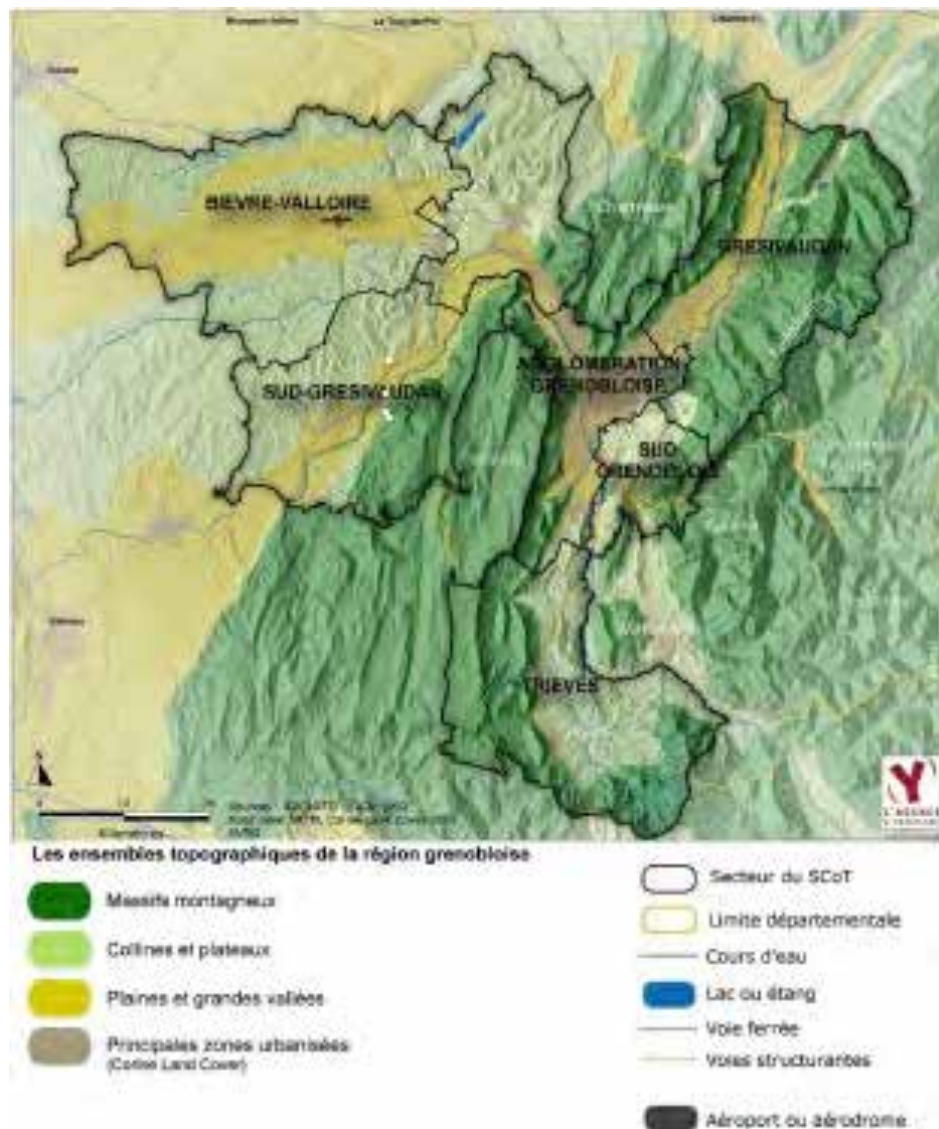

The “Loi de Modernisation de l’Action Publique Territoriale et d’Affirmation des Métropoles” MAPTAM law of 27 January 2014 has enabled urban all urban agglomerations with more than 400,000 inhabitants to have broad powers in terms of sustainable planning, economic development, housing and the management of mobility and local public services. Looking at Grenoble’s experience, guidance regarding the ways in which the territory is organised finds expression in the “Schéma de cohérence territoriale” and is the subject of various regulations, as part of the “Plan local d’urbanisme intercommunal”.

Part 2: Grenoble-Alpes Métropole, context and history of the construction of a sustainable urban development strategy

2.1 “Grenoble-Alpes Métropole au cœur des Alpes »

“Grenoble Alpes Métropole” has 445,000 inhabitants and is situated away from France’s major highways and rail routes. This isolation has been viewed as a limitation, one that the local actors have had to overcome in order to grow their businesses (Blanchard, 1935). The valley floor, at the confluence of the River Isère and the River Drac, is surrounded by three mountain massifs, the Vercors, the Chartreuse and the Belledonne, and has produced an urban site that is both complex and limited, as seen in Figure n°2. The lack of space explains the need to intensify urbanisation, which leads to both the compactness (3,673 inhabitants per km²) and especially density indices (8,500 inhabitants per km²) being rather high. The agglomeration is characterised by a juxtaposition of urban fabrics (historical centre, condominiums, single-family houses, large complexes, activity zones) that produce a composite landscape.

Figure n°2: Grenoble Urban Region and its territories

Source: Agence d'Urbanisme de la Région Urbaine de Grenoble, 2005.

Grenoble has been an industrial city since the mid-19th century. The city's tradition of scientific and technological innovation, based on an innovation ecosystem that links the university, research centres and industrial enterprises, has yielded a dynamic of technopolitan activities. Today, Grenoble specialises in software design and nanotechnology, and its economy is boosted by the presence of a dynamic university, large scientific facilities (Synchrotron) and international companies. However, its technological dynamism does not guarantee an urban dynamic since, between 2007 and 2011, the number of private salaried jobs fell 2.7%. (Novarina, Seigneuret, 2015).

2.2 Grenoble, a pilot city of the ecological transition

Because it lies in a basin, the city's urban area is facing acute environmental problems (pollution, global warming, an increased range of temperatures and other hazards) that compel it, perhaps more than others, to implement sustainable development strategies voluntarily. Grenoble has been involved

in a series of sustainable development initiatives since the beginning of the 2000s, for which it has received recognition at national and international levels. In 2001, the refurbishment of former military barracks in the Bonne district, in the immediate surroundings of the historical centre, combined the restoration of old buildings with new building projects. It was based on the use of renewable energies and the “Haute Qualité Environnementale” standard. This project enabled Grenoble to receive funding from the European Union as part of the Concerto programme, as well as the “Grand Prix EcoQuartier”, which is handed out by the Ministry of Ecology. At the same time, the municipality chose to include a guide to the environmental quality “Guide de la Qualité Environnementale de l’Architecture et de l’Urbanisme” in its “Plan Local d’Urbanisme”. Around a decade later, with the goal of creating a post-carbon metropolis, the agglomeration community obtained support from the Ministry of Ecology and the “Caisse des Dépôts et Consignations” (a public finance institution) for its “EcoCité” project, whose goal is to repurpose the technopolitan site of the Scientific Peninsula and facilitate greater social and urban diversity.

Up until 2015, the Grenoble urban district (the city centre and the inner-ring suburbs) had been organised as a “Communauté d’Agglomération” with limited powers regarding economic development and territorial planning. Its powers were limited to mobility, housing and the management of local public services. Competing interests between municipalities explain the local reluctance with regard to large-scale planning. Local actors long expressed a preference for a concatenation of experiences and specific projects that allow their communal singularities to be affirmed. As a result, territorial planning in Grenoble has been done by stratification and juxtaposition of projects.

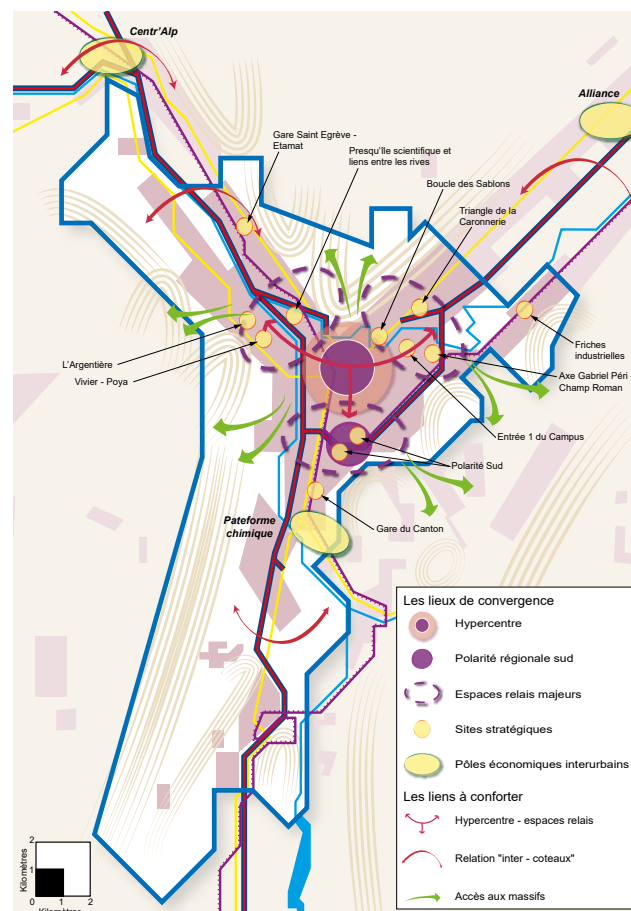

2.3 The “Projet d’Agglomération”: towards a polycentric territorial organisation

In order to grow and to guarantee that it will be a sustainable and innovative city, Grenoble took a positive path on which it is possible to point to cities that were trailblazers in this regard – ones that historically benefitted by finding investment and external financing that helped them get their projects off the ground. This yearning to increase the appeal can be noted in the many documents that make up the main stages of Grenoble’s territorial planning process on , whether it is the “Schéma de cohérence territoriale” (SCoT), the “Plan de déplacements urbains” (PDU), the “Projet d’Agglomération” (Acts I and II) or, more recently, the “Ecocité” (1 and 2) and the “Plan Local d’Urbanisme intercommunal” (PLUI) processes.

Over the course of sectoral inter-communal processes, such as the successive “Plans de déplacements urbains” (2000, 2007 and 2012) and the “Plan Climat-Energie Territorial”, professionals and subsequently elected officials gradually forged a common approach to sustainable urban development, an approach that may be described as pragmatic because it is built more in terms of the local context than on theoretical or doctrinal principles laid down at the outset. Also, while these documents were being drawn up, first the information, then the consultation, increased: Elected officials, technicians, inhabitants, associations and economic actors took part in discussions at negotiating tables (Forum 21, public meetings). Inter-communal mobility policies, related to those regarding housing and energy, have contributed to the building of a strategy of sustainable urban development that is shared between numerous actors across the Grenoble urban district. But there is no question that it was the “Projet d’Agglomération” that first offered a vision of the urban area and its development.

The “Projet d’Agglomération” does not have any binding effect. It came in response to a simple desire to supervise operational projects in communities and because of a search for coherence. At the time, there was still a gap between the guidelines as defined by the “Schéma de Cohérence Territoriale”, which had been developed for a vast urban region, and the operational projects that the municipalities were undertaking. The “Projet d’Agglomération” appears to be the preferred way of moving to an “Intercommunalité de projets” and to be in a better position to take advantage of funding opportunities. Based on the involvement of public and private actors, it presents itself as a framework for synthesising sectorial programmes (economy, transportation, sanitation and waste management, housing and urban social development, sports equipment), a partnership mechanism with the municipalities and the private actors, as well as a means of positioning the urban area in relation to others in France and around Europe. Thanks to a two-step process, the “Projet d’Agglomération” made it possible to organise an original stakeholder participation experience in building a common vision of the future of their territory. The process consisted of the adoption of Act I in 2003 and of Act II in 2007. While emphasising the importance of networks of natural spaces in the identity of the urban area and the need to intensify urbanisation in public transport corridors, the “Projet d’agglomération” was in favour of a polycentric organisation as seen in Figure n°3. Around Grenoble’s reinforced city centre (heart of the city and the urban area), there are three secondary polarities. Each of these polarities provides property opportunities for an equal number of sites of urban renewal to be developed within the framework of polarity conventions.

Figure n°3: The “Projet d’Agglomération”: a polycentric organisation

Source: Projet d’agglomération, Grenoble-Alpes Métropole, 2007.

2.4 From strategy to urban demonstration projects

The Ministry of Ecology and Sustainable Development's "EcoCités1" call for tenders in 2009 provided an excellent opportunity for Metropolitan Grenoble-Alpes to turn the goals of the "Projet d'Agglomération" into concrete actions and achievements. The desire of the ministry, and of the City of Grenoble, to favour projects that, on the one hand, could be built quickly and, on the other hand, would attract local economic actors resulted in only one test site being built: the Scientific Peninsula, located on territory that belongs to the city centre.

Driven by the City of Grenoble on the one hand and the local scientific and technical community on the other hand, Grenoble's "Eco-Cité1", even though it has met the criteria set by the French government to access funding, has taken a technical track. The Peninsula project is indeed an opportunity to develop technological innovations in favour of a sober and peaceful city, with a cooperative management of energy, the building of smart-grids and the implementation of the "Pass-mobilité" system, the "Ilot Urbain Intégré" as seen in Figure n°4. And actions in support of a "ville-intégratrice" and a "ville-nature" have been planned to bolster these innovations. However, the constant quest for innovation has led to technical solutions being sought to solve social and urban problems. In an effort to achieve immediate and exemplary results, it has led to a sectorial operational project being favoured at the expense of a metropolitan strategy and the importance of public debate being minimised when it comes to drawing up strategies and constructing projects.

Figure n°4: "Ilot Urbain Intégré"

Ilot Urbain Intégré maîtrise des consommations énergétiques et utilisation d'énergies renouvelables pour UNE VILLE SOBRE

L'Ilot Urbain Intégré, est privilégié :

- pour penser toutes les thématiques du projet (énergie, usages, mobilités, formes urbaines,...)
- pour rechercher une diversité des énergies à utiliser, une autonomie et une gestion collective de l'énergie sur une grille de partage intelligente, la smart grid.

Part 3: Grenoble-Alpes Métropole, territorial planning in motion

3.1 The “Plan local d’urbanisme intercommunal”

Following the change in the governing coalition in 2014 in the city centre,³ a new majority governing Grenoble-Alpes Métropole⁴ is making changes to the strategies and projects undertaken. The need to reinforce the urban area’s economic attractiveness is now being looked at more closely, and the public and private investments in a small number of big projects are receiving criticism. Thus, in addition to seeking efficiency and energy sobriety, the Grenoble actors’ strategy at the time they applied with “EcoCité 2” in 2015 is to open the game to the actors, help the consumers to better control their energy costs and push them towards becoming producers. At the same time, the change in status of Metropolitan Grenoble-Alpes on January 2015, when the urban community became a metropolis, led to a considerable expansion of powers and an obligation to draw up a “Plan local d’urbanisme intercommunal” (PLUi), which will replace the 49 communal/municipal plans on December 2019.

This “Plan Local d’Urbanisme intercommunal” seems to provide an opportunity to revise territorial planning.

- It defines new ways in which citizens can participate and proposes a new division of decisions between the inter-communal and the communal levels;
- It considers the diversity of spatial configurations at the metropolitan scale in order to develop a vision that makes the quality of life a condition for economic attractiveness;
- It takes new temporal constraints into account by taking up the challenge of producing a complex plan in a short amount of time (three years);
- It takes into account the challenges facing the metropolis: fighting climate change, initiating an energy transition, strengthening economic dynamism and reinforcing social cohesion in the territory.

3.2 New methods of participating at the level of the large territory

While for many years there has been consultation in Grenoble regarding operational projects that have an immediate impact on the inhabitants’ living conditions, planning on the scale of the large territory concerned the elected representatives as a matter of priority. The development of the “Plan local d’urbanisme intercommunal” is an opportunity for “Grenoble-Alpes Métropole” to replicate and amplify experiments in this area, conducted as part of the “Plans de déplacements urbains” and the “Projet d’Agglomération”. Thus, “Grenoble-Alpes Métropole” has renewed communication and consultation in a way that can be described as traditional. It has mobilised the usual means of information: articles in newspapers, displays and registers in town halls. It has also organised workshops according to the major geographical sectors and mobilised a Citizens Panel. In addition, the Development Council, which brings together citizens, representatives of employers organisations,

³ In Grenoble, the new majority comprises the Greens, the extreme left and representatives from NGOs.

⁴ While the president is still a Socialist, his party is in the minority in the new majority that also includes the extreme left, the Greens and the Communists.

trade unions and associations and represents, to some extent, the economic and social world, was invited to issue an opinion on the main guidelines of the “Plan local d’urbanisme intercommunal”.

However, fully aware of the limits of these traditional modes of doing things, the professionals in charge of the “Plan local d’urbanisme intercommunal” have resorted to more innovative means of communication. The consultation was organised particularly for inhabitants thanks to the creation of a digital collaborative cartographic platform. “Carticipe” became the “Plan local d’urbanisme intercommunal’s central consultation tool: It allows all of the city’s residents to geo-locate themselves and file an opinion, which the other inhabitants are called to vote on and speak out about, as seen in Figure 5. “Carticipe” made it possible to collect more than 2,012 contributions and to broaden the consultation approach to a large number of people in an effort to have a collective exchange and a production of syntheses. The result of the work, within the framework of the Territorial Workshops on the one hand and the Citizen Panel on the other hand, was also addressed in filings on this digital platform.

Figure n°5: Carticipe tool: interactive map

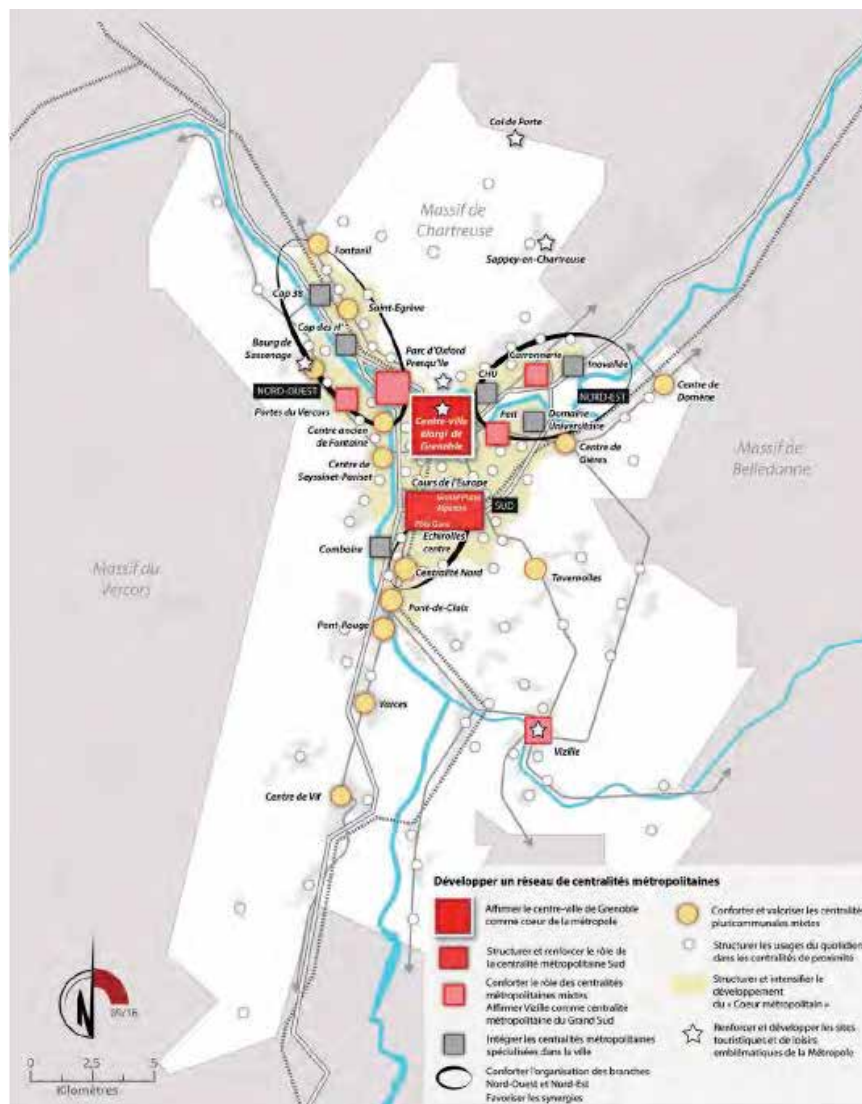

Source: Grenoble-Alpes Métropole 2018.

If the role of scientific and technological innovation in local development is brought out, the focus is on quality of life as a condition for attractiveness. “Grenoble-Alpes Métropole” is presented as a “mountain metropolis” that has to seek a way of better highlighting the diversity of its landscapes,

namely its urban core, as well as its valleys and surrounding mountain balconies. The fight against urban sprawl involves the creation of a polycentric metropolis by identifying three levels of centrality (proximity, inter-communal and metropolitan). The structure adopted by the “Projet d’Agglomération” is the subject of a new presentation aiming to take into account the complexity of a territory that was enlarged in 2015 when the community was made a metropolis, as seen in Figure 6.

Figure n°6: Network of the centralities on the metropolitan level

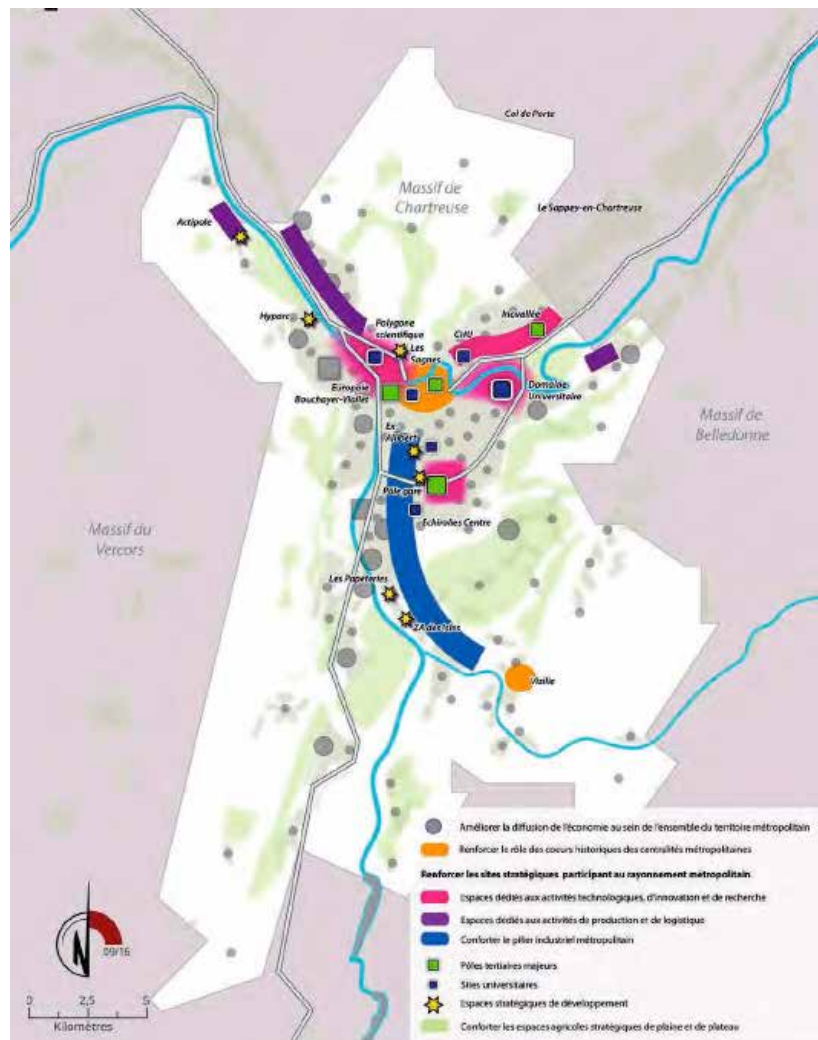

Source: Grenoble-Alpes Métropole 2016.

Economic development sites are no longer confined to the technopolitan spaces to the east (computers and software) and to the west (nuclear and nanotechnology) of the city centre but tackle the need to strengthen the metropolitan role of Grenoble’s historical centre, to take into account the industrial

pillar located in the south and to reinforce the presence of agriculture. The goal is, therefore, to utilise a variety of economic development pillars as seen in Figure n°7.

Figure n°7: Strategic sites on the metropolitan level

Source: Grenoble-Alpes Métropole 2016.

3.3 New temporality and finding flexibility

The obligation to draw up an urban planning document in a very short amount of time and on the scale of a vast territory comprising 49 municipalities initially seemed to be a constraint that professionals would find difficult to overcome but was ultimately revealed to be a real asset. It forces the planners to drop an approach that tries to be exhaustive because it seeks to treat the same level of precision all the themes that a “Plan local d’urbanisme” has to tackle.

Today, the idea is to consider the “Plan local d’urbanisme intercommunal” as the first step in a planning process that will have to take reversals of circumstances into account as much as possible. Thus, plans are made for regular changes in order to respond to municipalities’ requests and to incorporate mature projects. Additional studies may be undertaken at strategic sites as soon as

the “Plan local d’urbanisme intercommunal” is approved. The goal is to find flexibility in the different planning documents.

Discussions have also started regarding the implementation of the “Plan local d’urbanisme intercommunal”. Since the passage of the “loi Solidarité et Renouvellement Urbain” (SRU law) in 2000, there has been a possibility to put in place “Orientations d’Aménagement et de Programmation” (OAP). Unlike rules that have to be strictly adhered to when they are applied, these guidelines are less precise. They can be interpreted in various ways and negotiated when they are applied. The guidelines can be sectorial and can outline a project for a strategic site identified in the “Plan local d’urbanisme intercommunal”. They can be thematic and provide indications of public policy in a particular area. In “Grenoble-Alpes Métropole”, three thematic guidelines are in development: The first concerns the quality of the landscapes, the second takes risks into account in the context of a resilient approach to urban planning, and the third relates to recommendations that have to be kept in mind to limit the effects of air pollution in homes.

Stressing the need for flexible planning and emphasising its procedural nature is a paradigm shift for professionals who, until now, have been accustomed to taking the time necessary to draw up documents that are as comprehensive as possible. There is a desire to set the planning in motion and to make it a privileged means to drive actions and projects.

Conclusion

In a metropolitan context characterised by the fragmentation of institutions, “Grenoble-Alpes Métropole” had been forced to rely on sectorial actions and projects to produce a “Projet d’agglomération” at the intersection between a “Schéma de cohérence territoriale”, developed for the metropolitan area, and town planning projects by the municipalities. Following Parliament’s passage of the MAPTAM law, the “Grenoble-Alpes Métropole” changed status in 2015 (from “Communauté d’agglomération” to “Métropole”) and acquired broader powers than municipalities.

The drafting of the “Plan local d’urbanisme intercommunal”, which accompanied a growing openness by metropolitan and municipal elected representatives towards an ecological transition, corresponds to a moment of change for the territorial planning strategies concerning the urban area:

- The use of new tools favouring an opening of the participation process with Carticepe;
- the adoption of a new vision: a mountain metropolis rich in diversity;
- the construction of a new polycentric organisation;
- and the will to put the guidance above the rules;

demonstrate a willingness by the Metropolis to seek close cooperation with the municipalities and with private actors and the desire to promote a type of planning in motion that would be both proactive and flexible.

Abstract: Previous research has proven the necessity of an energy transition. More and more local visions on an energy neutral future are being adopted, powered by targets on different policy levels (UN, EU, national and local) and the Covenant of Mayors initiative in Europe. These visions are flanked by a series of concrete actions that should be established by either 2020 or 2030. A comparative analysis of the Sustainable Energy Action Plans (SEAP), submitted within the framework of the Covenant of Mayors, however shows that although the ambitions within these visions are frequently high when setting long term targets for an energy neutral future in 2050, actions on the short term often focus on low-hanging fruit. While these quick wins are necessary towards an energy neutral future, they will not be enough to create a real transition. There seems to be a missing link between ambitious visions and concrete actions.

This paper will argue that territorial actions are needed to reach the energy goals and fill in the gap between those first, successful, but relatively easy actions and a full-blown energy transition. Moreover, the general awareness of the importance of spatial planning, of integrating energy goals into every spatial project and connecting different scale levels is often missing. Reducing energy, increasing energy efficiency and increasing renewable energy can all be linked with territorial factors. Furthermore, governance, going beyond government and including private and civil society actors is needed.

Keywords: Spatial Development, Energy Transition, Governance, Mitigation

Introduction

This paper will use the Covenant of Mayors (CoM) initiative in Europe as an approach to analyze if and how the local government as an actor is contributing spatially to the energy transition. The goal of this paper is (1) to analyze the extent in which the guidelines and methodologies put forward by the Covenant of Mayors (CoM) are taking territorial factors like the influence of land use and planning measures into account and (2) to analyze to what extent the developed and submitted SEAP's in Flanders are using these territorial factors within land use and urban planning measures to implement their short term and long term goals. The first section will introduce the Covenant of Mayors (CoM) initiative as a means to achieve energy neutral cities. The second part will focus on the reciprocal relationship between energy and space and how spatial planning can influence our energy needs and production. Here, a framework will be introduced to analyze to what degree plans take spatial

elements into account. In the third part the guidelines offered to the local government on how to develop their Sustainable Energy Action Plan (SEAP) are reviewed focusing on the suggestions for spatial actions. Then we turn to our case of Flanders and first of all introduce the way the CoM is implemented in Flanders. In the fifth section an in-depth analysis is made on five specific SEAP's in Flanders and the extend in which they take territorial factors into account. This paper ends with a discussion, a conclusion and recommendations for further research.

The Covenant of Mayors initiative underlines the importance of local governments within the energy transition

Several authors (Bertoldi, Cayuela, Monni, & De Raveschoot, 2010; Croci, Lucchitta, Janssens-Maenhout, Martelli, & Molteni, 2017; Hakelberg, 2014; Kona, Bertoldi, & Kılış, 2019) stress the importance of local governments in achieving the global and European energy targets. Their potential is linked to a combination of local knowledge and power and responsibility (Melica et al., 2018). In 2008 the Covenant of Mayors (CoM) was introduced by the European Commission as a voluntary commitment to reduce municipal CO₂ emissions by at least 20% in 2020 or 40% by 2030. In order to achieve these commitments, municipalities engage themselves to develop and implement a Sustainable Energy Action Plan (SEAP) by 2020 or a Sustainable Energy and Climate Action Plan (SECAP) by 2030. While a SEAP only focusses on mitigation strategies and actions a SECAP also includes climate adaptation. By signing the CoM, municipalities commit themselves to follow standardized methodologies in setting CO₂ reduction targets and in designing and implementing policies and measures to reach these targets (Croci et al., 2017) and to submit a SEAP within the year following adhesion. Because at the moment not many municipalities have signed in for a SECAP this paper will focus on SEAP.

The first step within the CoM is to sign the agreement and committing to the reduction target of either at least 20% (2020) or at least 40% (2030). As a second step a municipality should make a Baseline Emission Inventory (BEI). This BEI indicates for each sector how much CO₂ is emitted due to energy consumption in the territory of the municipality in the baseline year. This inventory helps them first of all to identify the best field of action and the opportunities to reach the set goals (Bertoldi et al., 2010). Secondly, it helps them to monitor the progress linked to the third step of the CoM process. Differences in CO₂ emission levels between local administrations is mainly dependent on local specificities like urban form and landscape determining for instance potential for renewable energy generation, but also the possibilities for a modal shift. Climate conditions can furthermore influence the energy needs for heating and cooling (Croci et al., 2017).

The third step for a municipality is to develop and submit the SEAP itself. The SEAP should include actions of both public and private sectors, but since the municipalities themselves are the key players to implement actions, they mainly focus on their own buildings and infrastructures to act as role models for businesses and citizens. Since heavy energy-using installations like large power plants and industrial plants are part of the European CO₂ Emission Trading Scheme (ETS) (covering around 45% of emissions), these actors are excluded from the SEAP. The target sectors are buildings, transport, equipment/facilities, industry (non-ETS), local electricity generation (non-ETS) and local heating/cooling generation. As additional 'other' fields land use planning, urban regeneration, public procurement and participation are mentioned. These are the policy areas which a municipality can directly influence (Melica et al., 2018). The municipality is encouraged to distinguish between a long term vision towards 2050 and short term goals and actions towards 2020 or 2030. The vision for a sustainable future should be used as a guiding principle to make a SEAP together with the BEI.

As a fourth step the municipality should develop an implementation report and an action report. The implementation report contains information on the actions implemented and their impacts in a quantified way calculating the (hopefully reduced) CO₂ emissions. Part of the implementation report is a Monitoring Emission Inventory (MEI). The MEI follows the same methodology as the BEI. The action report on the other hand is a

more qualitative report about the implementation of the SEAP giving the status of the measures mentioned in the SEAP.

It is important to mention, especially for the next parts of the paper, that municipalities that are lacking capacities to make and implement their own SEAP can be supported by administrations or organizations that do have such capacities (Bertoldi et al., 2010) like a province or a region. These so called coordinators offer strategic guidance, financial and technical support to municipalities. Their existence has proven to support municipalities with less capacities to adhere (Melica et al., 2018; Pablo-Romero, Sánchez-Braza, & Manuel González-Limón, 2015). The three countries with the highest number of signatories (Italy, Spain and Belgium) also have the highest number of official coordinators (Melica et al., 2018).

Territorial factors are important to help the energy transition

Urban planning and land use planning are often overlooked areas to assist in reducing energy needs, increasing energy efficiency and increasing the integration of renewable energy forms in the landscape. Literature however indicates that urban form and locational factors are key influencers within the energy transition (Crocì et al., 2017; Seto et al., 2014; Van Den Driessche, Nijs, Rédelé, Oelbrandt, & Van Steenkiste, 2019; Van Noordt, 2018; Wauters, Dhondt, Fremault, & Corens, 2017). This section wants to list and elaborate on the spatial actions that can be taken by local governments and use it as an analytical framework to assess first of all the level of territoriality of the CoM in general and secondly the existing CoM action plans in Flanders. Five territorial factors will be further elaborated: (1) General awareness on the importance of a territorial perspective; (2) Energy Reduction; (3) Energy Efficiency; (4) Renewable Energy Production and (5) Governance.

General awareness of the territorial perspective

The first and most important step is to raise the general awareness of policy makers and practitioners on the fact that the link between spatial development and energy policy and goals is a very important one. This relationship works in two ways: the framework set out by energy policy has important consequences regarding the spatial design of our environment. Measures to reach the targets, like siting wind turbines or reducing the energy used in transport, need to find their 'place' in our environment. They literally need to 'land' somewhere. The other way around, spatial policy and urban design also determine the energy system, the amount of energy used and the potential for efficiency and production (Van Noordt, 2018). It is important that policymakers become aware of the fact that 'the energy transition' is not a separate project which needs to be developed independently, but instead should become an integral part of every project a municipality starts. Policies and measures should look beyond the building level and focus to connect different scale levels from building to building block, neighborhood, city, region, nation and even global. Connecting these scale levels and looking beyond the building will help to translate policy ambitions into concrete actions while at the same time making the abstract consequences of the energy transition very tangible for citizens. By thinking beyond borders, whether this is the border of a specific project or municipality borders, linkages, opportunities and synergies can be detected (Van Den Driessche et al., 2019).

Energy reduction

Reducing the amount of energy needed in the built up environment is dependent on four variables (Seto et al., 2014). These factors are of course interrelated and interdependent and need to be taken into account together to achieve the maximum energy reduction. The first element is density. When applied to the city scale, low density developments result in higher transport needs with greater distances. Furthermore, low densities make it difficult to promote sustainable transport types like walking, biking or public transport. High density urban fabrics on the other hand reduce distances and so reduce travel need and energy needed for traveling while also promoting

alternative transport types (Seto et al., 2014). Finally, density can also be applied on the level of a building. The energy use in a building and so the potential to reduce this energy use is mainly determined by the size of the building, the surface-volume ratio and the insulation. Building more compact buildings, in greater densities and with sufficient isolation would therefore reduce the energy needs (Wauters et al., 2017). The second factor in the built up area is land use mix. Land use mix refers to the degree of mixing of different functions in an area. For example mixing residential, business, commercial and green areas. By bringing these types of activities into each other's proximity the need for transport (eg need for energy) is reduced. Historically, land use planning adhered the opposite: to separate functions because of possible negative effects from industrial areas (Seto et al., 2014). Regarding increasing the land use mix, the highest gains are achieved when daily activities are located close to each other (Wauters et al., 2017). The third factor is connectivity. The level of connectivity in a city can be measured by the average size of a building block and the amount of intersections. When a city or neighborhood has a very fine grained infrastructure system with attractive footpaths and cycle lanes, walking and biking is promoted, which reduces the GHG emissions (Gehl, 2010; Seto et al., 2014; Wauters et al., 2017). The last element in reducing the energy needs in the built up environment is accessibility. This factor is closely related to land use mix, but also to connectivity. Accessibility can be defined as access to people and places in a city (Seto et al., 2014) and access to sustainable types of transport (Wauters et al., 2017).

Energy efficiency

A third group of spatial actions are focusing on increasing the energy efficiency. At the moment a large part of energy from burning fossil fuels is lost due to the inefficiency of the extracting methods we are using. The heat produced in a car engine is lost to its environment, making the percentage of actual used energy compared to the potential energy of gasoline only 25%. The same comparison holds up for using high quality of natural gas to heat our buildings: most of the energy potential of this energy source is lost (Sijmons, 2014). By linking different end users and using collective installations instead of individual ones, the energy need can be brought down to 1/5th of the need of individual users (Posad, 3E, Universiteit Gent, & Resourcedesign, 2016). By introducing collective installations more thought needs to be put in the localization of these installations, the connections to individual users and the overall urban design. This is connected to the actions introduced for energy reduction. A specific type of collective installations are heat networks. Because of the specific characteristics of heat, this energy mode needs to be generated close to the place where it is used (Wauters et al., 2017). At the moment, like stated before, much of the heat generated is lost as a by-product. By activating lost heat, but also by introducing heat cascades, the energy can be used more efficiently. A heat cascade makes sure that high temperature heat gets used in processes needing high temperatures, like industrial processes, while the residual lower temperatures can be used for less demanding usages, like heating buildings. By creating networks of heat cascades the same amount of energy can be used in multiple ways, losing less high quality sources (Sijmons, 2014).

Renewable energy production

Within the energy transition a switch needs to be made from using fossil fuels towards using renewable sources. The energy density, or the amount of energy per volume, of a renewable energy source is however much lower compared to fossil fuels (Sijmons, 2014). This means that in order to generate the same amount of energy from renewable sources as from fossil sources, more space is needed (Posad et al., 2016). Moreover, because of the more direct link between renewable sources and the end users, smart solutions to integrate renewable sources within our built up environment are needed. Furthermore, the potential to generate renewable energy differs from place to place. Wind energy can only be generated when there is enough wind, while deep geothermal energy is dependent on aquifers at the right depth. Regarding renewable energy, two elements are taken into account. First of all the integration of renewable *electric* energy sources like solar panels and wind turbines in the (built up) landscape must be considered. Two possible, but not excluding, strategies can be applied. First of all large scale renewable energy projects can be sited in the landscape, producing a large amount of renewable

electricity. But it is also possible to integrate smaller scale renewable sources into the (built up) landscape, like siting solar panels on existing roofs (Wauters et al., 2017). A second element of renewable sources that need to be integrated in the urban environment is heat. Like explained above, heat cannot be transported over longer distances, so siting new heat sources, using residual heat and linking varied sources with demand through a heat network is a very place-based project. Moreover, a direct link with densification strategies mentioned above can be made. A heat network becomes more profitable in densely built-up areas.

Governance

The complexity of the energy transition necessitates the involvement of other actors besides the government. Literature argues that for transitions in general a wide variety of actors needs to be involved (Avelino & Wittmayer, 2016). In order to mobilize the public opinion, suggest new solutions and to form strong coalitions private actors and civil society together with academia are needed (Lemos & Agrawal, 2006). When talking about governance it is therefore important to stress the fact that actions can be initiated by the government, but also by civil society, companies and NGO's (Boelens, 2010). Governance is therefore by definition multi-actor (Newell, Pattberg, & Schroeder, 2012).

Table 1 summarizes the five elements understood under 'territorial factors'.

Territorial Factor	Spatial Element
General awareness	Reference to land use planning / urban planning
	Integrating energy goals into every project
	Connecting different scale levels
Energy Reduction	Promoting densification & reducing urban sprawl
	Promoting mixed use
	Connectivity
	Accessibility
Energy Efficiency	Use of collective energy installations
	Investing in heat networks with heat cascades
Renewable Energy	Reserving space for large scale renewable energy projects
	Integrating renewable energy sources in the (built up) landscape - electricity
	Integrating renewable energy sources in the (built up) landscape – heat/cold
Governance	Involving all actors: public, private and civil society

Table 1 Summary of territorial factors which can assist to reach the energy transition

The Covent of Mayors guidebooks help local governments with their SEAP

The CoM initiative exists for over 10 years now. The developed insights during this period has produced two guidebooks for municipalities: one in 2010 (Bertoldi et al., 2010) and a new, recently released version in 2018 (Bertoldi, 2018a) (Bertoldi, 2018b), both published by the Joint Research Centre (JRC). The new version is much more elaborate, drawing on good practices from submitted SEAP's and adding the component of climate adaptation and the connected Risks and Vulnerabilities Assessment (RVA) as part of a SECAP. This part will analyze the territorial factors suggested in these guidebooks focusing on energy actions using framework explained above.

Both the SEAP and the SECAP guidebooks point to the importance of land use planning especially when developing a long term vision. The guidebooks show great awareness of the link between spatial planning and

energy actions in general. Both guidebooks have a special section dedicated to urban and land use planning. The energy transition should become a core element in urban planning (Bertoldi, 2018b). A reference is made to the opportunity to make cities more energy neutral with every new development project within the territory of a local government. Missing out on these opportunities will have lasting consequences for the future. The guidebook therefor advocates a thorough integration of energy related considerations in all new developments (Bertoldi, 2018a).

When referring to the reduction of energy needs the guidebooks explicitly connect urban planning with transport. The actions to achieve this goal are to make more efficient use of space by promoting a compact city and targeting urban development to public transport, cycling and walking. Spatial planning is also stated when the attractiveness of alternative transport modes needs to be increased by delivering the required loading factors. Moreover there is a role for spatial planning in providing enough space for cycling and walking (Bertoldi et al., 2010). According to the guidebooks, land use planning has a key role to play to avoid urban sprawl, promote compact urban settings and mixed use. On the scale of buildings, planning regulations have an important role for the amount of energy used for heating, cooling and lighting. Adequate orientation and arrangement of buildings, building blocks and green elements can significantly reduce the amount of energy needed (Bertoldi et al., 2010). Moreover, by reducing urban sprawl, green and rural areas are preserved which may potentially provide carbon sequestration. What is interesting to see, however, is that the first guidebook on how to make a SEAP sees urban planning and regulation only important for new buildings, but less relevant for renovated buildings and not relevant for existing buildings (Bertoldi et al., 2010). The second guidebook also refers to urban regeneration by revitalizing old brownfield sites and to 'Ecodistricts' (Bertoldi, 2018b). Although the second guidebook goes further into which spatial actions are possible they both mainly refer to 'new' developments, either on formally used, but now abandoned sites, or on completely new sites. By referencing spatial planning towards buildings in this way, the guidebooks overlook several ways how spatial planning can influence the energy performance of the urban fabric, like explained above. By downgrading its importance it is also less likely for a municipality to actually use spatial planning as an instrument.

Regarding energy efficiency, actions like promoting local electricity production to avoid transmissions losses and the promotion of district heating and cooling are put forward. Heat mapping is promoted to help determine where heat surpluses and heat demands are and to create robust energy strategies (Bertoldi, 2018b). Urban density and limiting sprawl are connected to opportunities for district heating. Other references are more on a regulatory level like modifying regulations to support heat pipelines through public spaces or shortening the time to obtain permits for renewable energy sources (Bertoldi et al., 2010).

According to the guidebooks, a careful planning of urban form can enable the production of renewable, low carbon and smart energy, while at the same time ensuring access to sustainable and secure energy supply. Like mentioned under energy efficiency, the guidebooks indicate the possible deterring effects of planning regulations on renewable energy projects. Complicated authorization procedures could become obstacles to promote renewable energy. Land use planning is also connected to the availability of space to achieve renewable energy projects. By using specific zoning laws certain areas can be safeguarded to be used for the installation of renewable energy sources. In order to select these areas a careful, integrated planning process is needed. The focus for energy generation is mainly on the possibilities there are within the municipalities own estate, or by public-private partnerships where the municipality plays a crucial role (Bertoldi, 2018b). Again, setting the right example is put forward as key for convincing its citizens. Community cooperatives are highlighted as projects which can enable citizens to have collective ownership, but in order for cooperatives to become successful there needs to be a certain level of citizen engagement and empowerment.

The guidebooks both stress the fact that a SEAP should not only focus on the local government itself, but all members of society should be involved to establish a common vision for the future and figure out how to achieve this common vision. Therefore, a SEAP should also include actions from the private sector (Bertoldi et

al., 2010). Moreover the guidebook calls the adhesion and participation of civil society as essential. The recommendation is to involve civil society in the elaboration, implementation and follow up of the SEAP. Especially the guidebook from 2018 refers to the concept of governance and the contributing roles of the private sector, academia and civil society (Bertoldi, 2018a, 2018b).

Support from regional, provincial and intercommunal level helps Flemish cities and municipalities submit their SEAP

Belgium is among the Member States with the highest number of signatories together with Spain and Italy (Melica et al., 2018). When looking at Flanders, 251 of the 300 municipalities have signed the CoM (Covenant of Mayors Office, 2019). What is even more interesting is that Belgium also has the highest number of Covenant Territorial Coordinators (CTC). These coordinators support local governments by providing strategic guidance, financial and technical support.

The Flemish government supports the municipalities by providing a website which offers datasets and tools. First of all inventories of CO₂ emissions are provided as an excel-sheet for each municipality for the years 2011 – 2016 and updated yearly. These inventories can be used to produce the BEI and MEI of each signatory. If they want, municipalities can also change the pre-made inventory by adding own data (Meynaerts, 2013). In addition, a ‘measures tool’ is offered. This tool suggests 10 example measures which can be taken to reduce energy use and thus reduce the CO₂ emissions. The actual reduction of CO₂ emissions for these measures is also calculated in an excel-sheet depending on the degree of implementation of the measure (Meynaerts, Renders, & Beckx, 2013). The example measures are all very much focused on individual buildings while the larger scale and possible measures related to urban and land use planning are not suggested. The tool mainly focusses on calculating CO₂ reductions. Although the suggested measure are of course only examples and municipalities are free to add their own measures in their SEAP, example measures given by a higher hierarchy could be very leading, especially for those local governments lacking the capacities to elaborate their own SEAP.

In the whole of Belgium 20 CTC’s are registered, of which 8 provinces. In Flanders, all the five provinces have signed up as a CTC as well as seven intercommunal organizations. The province of Vlaams-Brabant and Limburg for example offer extensive support towards their municipalities. In addition to pointing to the inventory made at the regional level they also offer a guidance document on how to make a SEAP in Dutch. This guidance document follows the same logic as the first guidebook offered by JRC, which means spatial planning is seen as an optional sector for measures to implement (Provincie Vlaams Brabant, 2014). Together with this document they offer a list of possible measures which is much more extensive than the list offered at the regional level. The downside however is that this list does not automatically calculate the reduced CO₂ emissions. The list of measures includes: limiting urban sprawl, Transit Oriented Development (TOD), improving fine grained connectivity, supporting collective actions at the neighborhood level, research into the use of residual heat and heat networks, land use regulation measures like compact neighborhoods, active search for space for renewable energy sources, integrating energy transition principles into land use planning and area developments (Provincie Vlaams Brabant, 2015). Overall this list is very comprehensive and seems to integrate the territorial dimension quite well. As a last document the Province also offers a model of a SEAP containing a base text and guidance which the local government only needs to fill in (with the help of the inventory and the measure list).

In-depth analysis of 5 SEAP (Brugge, Gent, Antwerpen, Leuven, Hasselt) and their territorial dimension

The previous parts have first of all argued why territorial factors are important to reach the energy goals, secondly concluded that the guidebooks made available for municipalities mostly follow the insights derived from literature regarding the role of urban and land use planning and thirdly ascertained that Flemish

municipalities are very well supported by both the regional level by providing data and tools and the provincial and intercommunal level by helping them to make and submit their BEI and SEAP. This part wants to look into further detail to what degree SEAP submitted by Flemish cities follow the advice from the guidebooks. To do this, a selection of the SEAPs of the five Flemish provincial capitals is made. Because of the general larger size of these cities and thus the bigger capacity, it can be expected that these SEAPs will be more comprehensive and elaborate compared to the SEAP of other, smaller municipalities. This analysis will however provide us with a first insight into the territoriality of Flemish SEAPs.

The city of Hasselt, with 78.000 inhabitants, follows the model offered by the Province of Limburg for their SEAP. The overall goal of Hasselt is to reduce their CO₂ emissions with 20% by 2020, with a focus on reduction through the switch towards renewable energy. Hasselt choose to include spatial planning as a sector to take into account in their SEAP, showing their general awareness of the importance of spatial planning. Location policy is put forward as crucial for a sustainable development. Mobility is taken into account by making sure new developments are served by public transport. Within the other sectors actions like applying the principle of compact and efficient use of space, introduction of a heat network, looking into possibilities to apply a neighborhood approach, linking spatial planning to the realization of sustainable mobility policy, by reducing the need for cars and improving soft mobility infrastructure and maximizing the amount of wind turbines are put forward. A communication strategy needs to make sure citizens and other stakeholders are involved and can participate (Stad Hasselt, 2012).

The city of Leuven, with 101.000 inhabitants, drafted their SEAP with assistance of the KU Leuven and has set a goal of 22% CO₂ reduction by 2020. The SEAP is part of a long term process towards an energy neutral city of Leuven by 2030. As a part of this road map a structure will be set up involving the city, the private sector, academia and civil society, covering the governing aspect. One of the actions which is put forward is to turn Leuven into a bicycle city and to significantly improve the public transport possibilities. Areas which lack a sufficient degree of services should be upgraded to avoid unnecessary transport. In general the city has the ambition to promote mixed land use and compact development. Regarding new developments, priority should be given to realization within the existing urban fabric by densification. Furthermore, 10 wind turbines and 10 small scale heat networks fueled by pellet stoves should be installed (Stad Leuven, 2013). Land use and urban planning is not explicitly mentioned nor taken up as a separate sector, but some of the actions do refer to the territorial factors. The document of Leuven also explicitly states that it should be regarded as an interim document and that the city will develop a more elaborate action plan towards 2030.

The city of Antwerp is the largest city of Flanders with 523.000 inhabitants. It wants to become an exemplary city regarding sustainability. On the long term, Antwerp wants to become a CO₂ neutral city by 2050 and have at least 20% reduction by 2020. The SEAP elaboration involved a large group of people ranging from policy makers to private sector and civil society. The SEAP also stresses the importance of all these different actors in the implementation of the actions and has the ambition to have an integral approach. A separate section is devoted to spatial development with an overall goal to integrate sustainability and energy within spatial policy. The goal is to reach a spatial structure that encourages soft transport modes and public transport, compact buildings and neighborhoods with high densities, mixed use and heat networks and to create possibilities for the siting of renewable energy sources. The harbor of Antwerp is put forward as an area with high potential for the development of both solar parks and wind turbines, while heat networks mainly seem interesting for new developments (Stad Antwerpen, 2011). The SEAP of Antwerp seems to be an exemplary case in which an integrated, spatial approach is put forward to reach their goals.

The city of Gent, with 260.000 inhabitants, also wants to become one of the good example cities in Flanders regarding sustainability. The city of Gent was one of the first cities in Flanders to approve a local energy plan. Because of this early adoption, it was not yet sure about their own energy impact nor about the most efficient measures to implement. The whole document is there for conditional and will be further elaborated during its

implementation period. As an overall goal a CO₂ reduction of more than 20% by 2020 is put forward, with more specific goals for the administration of the city. The city sees cooperation with its citizens, companies and visitors as essential. The city wants to act as the initiator and stimulator. With this approach they want to show that the energy transition is a common responsibility. For new developments a sustainability note needs to be made and at least one project needs to be realized that can serve as an example on sustainability. The city also wants to develop a 'wind-plan' for the entire territory of the municipality taking the 'wind-plan' for the harbor of Gent as a starting point. The SEAP does couple mobility reduction with land use, but no concrete actions, besides the development of bicycle lanes are suggested (Stad Gent, 2008).

Lastly, the city of Brugge, with 118.000 inhabitants, has developed its SEAP with support of two external companies. The overall goal is a reduction of 20% by 2020. The city has put great emphasis on participation, working together with citizens and businesses to define the policies and measures that need to be put forward in the SEAP. In its SEAP, Brugge refers to the guidebooks of JRC as an inspiration for the selected measures, while the inventory of the regional level is used for its BEI. The document is referencing scientific literature and acknowledging the fact that taking only small steps will not be enough to evolve towards a climate neutral city by 2050, therefor the SEAP and its measures is combined with a long term vision. One of the focal points is spatial planning which needs to be organized around energy-neutral nodes based on public transport axis, while the use of cars needs to be minimized and the shift to biking and walking promoted and the use of 'green heat' should be investigated. Concretely, 35 measures are put forward. Brugge wants to realize 30 wind turbines on its territory, expand its existing heat network and wants to introduce micro heat grids in the historic center (Stad Brugge, 2015). A more concrete elaboration on the energy-neutral nodes is however missing.

Discussion and Conclusion

This paper wanted to analyze to which extend territorial factors are taken into account in local energy action plans in Flanders. Since most of the municipalities of Flanders have signed up for the Covenant of Mayors (CoM) initiative, local SEAP's were taken as the focus for this analysis. A first step was to produce a framework to analyze these territorial factors. With the use of this framework the guidebooks offered by the JRC were examined. Overall these guidebooks offer a very comprehensive overview of how to make a SEAP. When focusing on the possibilities of land use planning and urban planning the guidebooks also refer to the insights other literature sources offer on the connection between the spatial dimension and reaching long term energy goals. The actions offered, like increasing the urban density, promoting mixed use and offering space for renewable energy sources, are however more complicated to reach compared to other measures and therefore require more skills and more commitment. The focus, especially in the first guidebook was mainly on the very concrete actions municipalities could undertake themselves to improve the energy performance of their own buildings. Defining and implementing land use measures seems to be the next step. Moreover, regarding the built-up environment, measures for new developments are suggested, while the existing urban fabric seems to be neglected.

Turning towards Flanders, the support from the regional, provincial and intercommunal level seems to be very well developed to support local governments in drafting and implementing their SEAP. Although the data and tools offered by the regional level does not seem to be very aware of the territorial dimension of the energy challenges, the provincial level does take these types of actions into account. The actions suggested regarding land use and urban planning, although they do follow insights from literature and the suggestions from JRC, are however not very visible and more or less 'hidden' in between the multitude of actions suggested. The five analyzed SEAP's all take territorial factors into account, although in different degrees. This general awareness, however does not always translate into concrete actions. Moreover, even when actions are proposed, they often stay very high level without a very concrete elaboration.

Land use and planning measures are very complicated to implement, this therefore seems to be a step not many municipalities are able to take (yet). As a consequence, at the moment actions on the short term often focus on low-hanging fruit, like changing to LED lighting or focusing on the energy reduction in the municipalities own buildings. These quick wins are rightfully part of an action plan towards an energy neutral city, but they will not be enough to create a real transition. Moreover, actions focusing on land use often take a long time period to implement and also have a long-term effect. This means that policy and measure on this theme need to be established now, otherwise energy inefficient development realized today will have consequences regarding energy efficiency for generations to come. Furthermore, wrong developments now could trigger a lock-in effect, which hampers a full transition towards carbon-neutrality. When analyzing local energy policy documents there seems to be a missing link between ambitious visions and concrete actions.

Further research on the action reports and implementation reports (MEI) would provide additional in-depth insight into the territorial factors and into what extend the actions put forward in the SEAP's are achieved. Since the goals set are for 2020, a more elaborate evaluation should be made in the next couple of years. The insights gained until now should however not be overlooked. They can already provide valuable input for the SECAP's which need to be made and implemented by 2030. Moreover, this paper only looked into the SEAP's of the five provincial capitals, more insights could be derived from an analysis of a more representative sample, including smaller municipalities. It can be expected that smaller municipalities in general lack the capacity to elaborate and implement a SEAP. The support given by the provinces and intercommunal level, might be helpful for the elaboration of a SEAP, but the implementation requires even more support.

This paper has put governance forward as one of the key factors for the energy transition. While some first insights regarding the public sector were given, more in-depth research is also needed for the private sector and civil society. The framework elaborated above, with territorial factors can also be used to analyze actions from these actors.

Sensing older people's lived experiences through visual images in Singapore

Belinda Yuen¹

belinda_yuen@sutd.edu.sg*

Abstract: This paper presents a user-based qualitative research approach: 'see and snap' to gain insights into older adults' lived experience of their neighbourhood environment. The method provides a way of capturing personal observations from the older population by involving them to take photographs of their built environment. The purpose is to allow participant photographs to query the built environment, in particular, how the built environment is perceived, negotiated and experienced during daily journeys. The discussion presents findings on older Singaporeans' (age 55+) daily travel experience, exploring what they see and think to be important environmental features for their ageing process. Such information has relevance to the wider discourse on healthy ageing and planning. Even though photographs are increasingly used as a research tool across a wide range of disciplines, e.g. anthropology, sociology, geography, few have used them with older people in cities. This 'see and snap' photo-taking method is part of a larger, multi-method study to understand the connection between older people's health and their neighbourhood built environment in Singapore.

Keywords: user photographs; neighbourhood; older population; Singapore.

Introduction

This paper presents a user-based qualitative research approach - 'see and snap' to gain insights into older adults' lived experience of their neighbourhood environment. It is one of three urban audit methods developed as part of a research project on "Understanding the Changing Needs of Singapore's Older Adults"; the other two methods are On-site Observation and Walk and Talk (see Yuen, 2019). The purpose is to investigate the older population's usage of their neighbourhood built environment and identify potential barrier and enabler in the design of current outdoor urban environment for ageing.

The premise of the 'see and snap' approach is the visual narrative research method, which involves the use of participant photographs as discussion materials during a research interview (Wang and Burris, 1997; Pain, 2012; Glaw, et al., 2017). As Glaw et al (2017) summarised, the use of photographs in interview offers a novel approach to accessing the rich everyday worlds of participants. Even though photographs are increasingly used as a research tool across a wide range of disciplines, e.g. anthropology (Collier, 1987), sociology (Banks, 2001; Harper, 1997; 2002), geography (Smith and Barker, 2000; Oldrup and Carstensen, 2012), health research (Hanna and Jacobs, 1993; Riley and Manias, 2003; Glaw, et al., 2017), few

have used them with older people in cities (Magilvy, et al., 1992; Yankeelov, et al., 2015; van Hees, et al., 2017). In Singapore, district level town councils in collaboration with various government agencies have started to conduct photograph-based participatory town audits to identify physical hazards in residential neighbourhoods and suggest improvements (Ministry of Health, 2014).

The rest of this paper presents an example of the method used in a study of older adults (aged 55 years and older) in Singapore. Like many cities around the world, Singapore, a city-state of 710 sq km in Southeast Asia, is ageing rapidly. Its age-65+ population is projected to double to one in four (900,000 people) by 2030. For many, the built environment for growing older is in high-rise public housing where 80% of resident population live (Yuen and Soh, 2017). Based on new town planning, each public housing town is designed along neighbourhood lines with a hierarchical range of retail (e.g. shops, markets), educational (e.g. primary schools, kindergartens), healthcare (e.g. polyclinics, clinics), transportation (e.g. mass rapid transit stations, bus stops, bus interchange), community, recreational and social amenities (e.g. parks, children's playgrounds, swimming pools, outdoor fitness equipment, senior activity centres) to cater to the daily needs of residents while providing a quality living environment (Yuen, 2007).

Method

The research activity of 'see and snap' involved two components: a photo-taking activity and a follow-up discussion. It was completed with a purposive sample of 17 older public housing residents (aged 55-70+ years) in a local neighbourhood from Jul 2015 to May 2016. The research protocol was reviewed and approved by the SUTD Institutional Review Board. Participants could choose to discontinue at any point of the research process and their data would be accordingly omitted from the study. In this study, an initial 22 participants were recruited and 5 decided to discontinue the study as they found the photo-taking activity onerous.

Participants were asked to use their camera-enabled smartphones to take photographs of their neighbourhood built environment as they went about their daily activities for one week. The aim was to collect older adults' place-bound, experiential knowledge about their neighbourhood built environment. Participants were, however, not required to do anything special or go anywhere outside of their daily routines and activities. The photographs could be of the built environment features along their travel journeys and/or destinations, e.g. their favourite places or regularly visited places, capturing the environmental features that they like or dislike about these places/routes, their concerns about the built environment and the features they view as important for their ageing process. During photo-taking, participants were encouraged to take note of the time and place where the photograph was taken and to submit these with a short line on why they had taken the photograph to the research team.

Each participant was invited to participate in one follow-up discussion session. Held within a couple of weeks after photo-taking was completed, the discussion was designed as small group discussion at the convenience of the participants to facilitate collective visualization of their experiences and views through the photographs, offering an opportunity for the less literate participants to also share their perspectives. A common discussion guide was used though the emphasis was on using the photographs to guide and encourage the participants to share their personal experiences of the built environment - which and why certain built environmental features matter to them/not. The discussion was audio-recorded with participant permission for transcription purposes. Where permission was not given for recording, instant notes were taken by the research team. The average duration of the discussion was between 1-1.5 hours.

The discussion was held in the preferred language of the participants – English or Mandarin. It should be noted that older Singaporean’s spoken English might not be grammatically correct to the native English speaker.

Results

Photo-taking was a new experience to some older adults. Yet, they patiently participated and took photographs to show and tell their experiences and memories with the research team. They sent an average of about 38 photographs each over a period of 7 days. The description that they provided with each photograph was a useful prompt for them to recall the context of the photographs during the follow-up discussion session.

As seen in Table 1, many of the photographs were about immediate neighbourhoods (5 of 7 photograph categories) while in some cases, they showed places beyond individual neighbourhood (e.g. traditional ethnic/cultural/religious places in other parts of Singapore) and about participants’ travel journeys by public transport or on foot (none of the participants drove or cycled). Discussions with the participants revealed that most of them were long-time (over 20 years) residents, at least two were in employment and the rest were either housewives or retirees. All participants were Singaporeans or permanent residents and physically mobile.

Table 1: What did participants take photographs of?

Photograph Content	No.	%
Outdoor green spaces, e.g. neighbourhood park, community garden	167	25.3
Transportation and travel journeys, e.g. sheltered walkway, longer crossing time for older adults, steps and ramps	122	18.5
Amenity and facility, e.g. marketplaces, eateries, shopping areas, library	117	17.7
Incidental social space, e.g. void deck, common corridors in public housing residential blocks, en route to key destination e.g. market, school, park	83	12.6
Favourite or frequented activity node outside of one’s neighbourhood, e.g. to visit friends and relatives, workplaces, medical care, leisure and recreation, cultural and religious places	63	9.5
Structured social space, e.g. exercise hard court, children’s playground, community centre	60	9.0
Quality of neighbourhood infrastructure and outdoor street furniture, e.g. lighting level, condition of benches, littering, maintenance	49	7.4
	661	100

Participants talked not only about the provision and setting but also the activities and meanings they attached to places. A frequent theme was outdoor green space, ranging from neighbourhood parks to community gardens and landscaped areas around the neighbourhood (Photo 1). Participants talked about community involvement in greening, community gardening

and nature maintenance; the community gardens were one of the favourite and most frequented places. They spoke about the role of their district mayor in championing the provision of community gardens. In consequence, their town now had more than eleven community gardens, spread across the neighbourhoods in convenient locations close to the residential blocks. Even though edible fruits and vegetables were favoured by many community gardeners, many of the community gardens had evolved special focus over time – some were for organic farming while others were spice garden, had medicinal herbs or special varieties of fruits trees and flowering plants.

Photo 1: Neighbourhood green spaces (all photos from respondents)

Zhenghua Park near residential blocks, a platform for exercises

Resident at community garden

Landscaping brings garden and greenery near to residents

Retirees engaged to do landscaping upkeep

Participants commented that they were able to have a sense of ownership as they took care of their own plot of garden and chose their preferred plants, vegetables, flowers or even medicinal herbs. They could enjoy the “fruits of their labour” as gardeners would get to keep the produce. Many opined that it was healthy to eat vegetables that they grew themselves (organic food). Importantly, for many, it brought back memories of days when they or their families were farmers.

Participants spoke about activities (soft programming) that brought residents to the community garden, park and green spaces. One respondent shared that she found it useful for residents to learn about gardening tips. The more experienced gardeners would sometimes share gardening tips on the types and names of vegetables, how to plant and harvest various kinds of vegetables. For some, gardening had become an integral part of their daily routines, something to do before or after their morning or evening exercises, morning trips to the market or before some of them go to work. For them, the community gardens supported social interaction, a place to meet other residents in the neighbourhood who shared similar gardening interests and through that helped them to make new friends and strengthen the sense of community. Some would take part in competitions such as for the best community garden in the neighbourhood. As one respondent proudly shared,

the community garden beside Block 423 is very good, was done beautifully. It is able to

win the first place in competitions! – Madam C, Chinese lady.

Others talked about the organisation of community programmes like ‘Sports to Stay Fit’, which took place every morning from 6.30am-8.30am, to encourage the participation of residents, mostly housewives and retirees for group exercises such as qigong. They also highlighted the provision of hardware infrastructure such as pavilions and seating, in particular, the absence of provision that discouraged their participation. For instance, some participants shared that their neighbourhood park lacked colour (a variety of floral planting), attractions and amenities for older adults to spend their spare time. More specifically, the lack of toilets in the park was an inconvenience, especially to the older person. One respondent highlighted the difficulty experienced by her mother,

...my wheelchair-bound mother has to rush back home because there’s no toilet in the park. It puts a lot of pressure on the old folks. – Madam HS, Chinese lady.

Others talked about the resulting adaptive behaviour. For example, one participant said that many of the people would just go home or to the shopping mall after their exercise to use the toilet, as it was close by the park. Two of the participants shared photographs showing some residents, mainly retirees who were hired by the town council for landscape maintenance work around the neighbourhood (Photo 1). It was understood that these senior citizens could choose the days and frequency in which they want to work. The participants felt that this was a good option for senior citizens who might want to engage in some work within the neighbourhood and who would otherwise be bored at home. As this respondent explained,

They are working as gardeners under Town Council... My husband is in charge of the workers there... Some of them, maybe the ladies, (work) only half a day. Only senior citizens (are employed). After retiring have nothing to do, might as well better they go out and work right? - Madam S, Malay lady.

Besides green spaces, another frequently visited place in the residential neighbourhood were food places.

Three-quarters of the participants commented that markets and local food establishments (Photo 2), e.g. *kopitiams* and hawker centres, were places that they would frequent on a regular basis – daily, several times a week, or weekly, usually by walking. *Kopitiams* are a type of food establishments, which are ubiquitous in Singapore. They are of a smaller scale than the hawker centre (often co-located with the wet market) and can be found in every neighbourhood, frequently at the void deck of public residential blocks. Aside from visiting the market and food places for grocery and for meals, participants viewed these places as social spaces to meet neighbours and people from the community. It was a place where they could stop, linger and sometimes watch the world go by.

Photo 2: Frequently visited neighbourhood amenities (all photos from respondents)

New Bukit Panjang Market and Hawker Centre

Library

Kopitiam

Pasar (market place)

Neighbourhood retail

Participants talked about how housewives and retirees (including themselves) could often be seen in these places, passing time, chit-chatting (among women), playing chess (among men), etc., enabled by the provision of seating, television set (in some *kopitiam*) and the availability of food and drinks. These neighbourhood food places were valued for their ease of access, convenience and low cost. Most participants informed that they could reach these places by walking. They were able to get a wide variety of daily necessities without the need to travel elsewhere. As one participant explained why a particular shopping mall was her favourite place in the neighbourhood,

Because the reason we have everything there (sic). We have market, we have clinic, and we have stationary shops. And we have provision shops. We have everything we need. Everything is there, so we don't have to go anywhere (else). And the MRT station is nearby for all the people (living in flats) ... I'm staying in Block 452, next door is the shopping centre. It's convenient. Everything is there. And the clinic is there. For the elderly people, the PG¹ clinic is also there so no need to worry; dental is also there. Everything is there. So I don't have to go anywhere (else). – Madam R, Indian lady.

Another participant spoke about her appreciation of long-time shop owners of various trades in her neighbourhood; these businesses not only offered convenience for residents in the neighbourhood but were also a familiar presence within the neighbourhood. There were interesting instances of specific local knowledge that some participants had, which would not

¹ PG refers to “Pioneer Generation”, i.e. Singaporeans aged 16 and above in 1965 or those aged 65 and above in 2014, who contributed to Singapore’s nascent years of nation building. Singapore had initiated a PG package for this group of older population to help with their medical costs; a PG card allows the cardholder to receive subsidised medical treatment at designated clinics.

be immediately apparent to outsiders. For instance, one participant talked about a particular vegetable stall in the market that sold vegetables grown in his own farm and her periodic haircut sessions to a neighbourhood hairstylist who worked out of her flat.

Other community amenities that participants liked included the community library, places of worship (e.g. churches, mosque and temples), senior activity corners, clinics and even traditional Chinese medicine (TCM) clinics in the neighbourhood. A couple of the participants wished for more senior activity centres to be located at their void decks. One participant spoke about the growing popularity of TCM clinics with older residents and the importance of including this amenity in the local neighbourhood,

Oh, this is the best. Nowadays, old people like to visit the TCM, and now it's so near our homes. We don't need to wait for the children to fetch them there or travel for long on public transport. We can just walk for a little bit. It is just behind the CC, Zheng Hua TCM. It is very convenient for the elderly. – Madam SB, Chinese lady.

Another added,

Before this, the nearest TCM was in Yishun. The doctor's skills are also really quite good. He is proficient at acupuncture and even massage. – Madam AP, Chinese lady.

About half of the participants who talked about footpaths indicated that they walked every day. They highlighted the importance of sheltered walkways that connected residential blocks to destinations such as bus stops, MRT stations, shops and wet markets, perhaps because of Singapore's hot and wet tropical climate. A handful of them expressed appreciation of the general landscaping and greenery efforts around the neighbourhood – along main roads and even at traffic lights (flower shrubs there are beautiful). For a couple of them, they would prefer to do their brisk walking along the footpaths of the main roads rather than to go to a park as the former was pleasant enough for exercise. Participants further talked about staircases, steps, inclined slopes and handrails that enabled them to move from one level to another. They often suggested replacing the staircases with ramps to support ease of movement.

Some elaborated on how some of the design features around the residential blocks did not contribute to a barrier-free environment. One participant cited the example of barriers erected to prevent cyclists or motorcyclists to ride on pedestrian paths but unintentionally could cause obstruction for some pedestrians like wheelchair users. The respondent explained with a Mandarin caption to his photograph that could be translated as,

The barriers are installed to increase accessibility but instead, added an additional obstacle. I would suggest for them to be removed. (Mr P., Chinese man).

Another respondent underscored the importance of safety in the design of elder-friendly public spaces,

(I would) like to have a safe environment for us (the elderly), and not only for us but for everyone. When you want to design anything, you want to make it good for all the people, (with) elderly people in mind – safe and not complicated. Don't make it so complicated that the elderly cannot use. I mean if you have all these features and you don't know how to (use them, it is it useless), just like a gadget... You think all the elderly know how to use all the sophisticated gadgets? They don't know it! Just to make it safe and easy to use for them. – Madam AR, Malay lady.

Other disliked aspects of the built environment were about the maintenance and upkeep of the neighbourhood, e.g. damaged park benches not replaced (do not have backrest for older users), rubbish not cleared promptly, recycling bin misused as rubbish bin (Photo 3). Several issues concerned the inconsiderate behaviour of other residents, e.g. neighbours who clutter and obstruct public passageways when they place their overgrown plants, shoe cabinets, clothes-drying racks, etc. in common areas. Others pointed out that in a high-density living environment and a multi-racial, multi-religious city like Singapore, there were some cultural or religious practices that when carried out in public spaces could spark inconvenience and cause unhappiness to others. One respondent gave the example that people sometimes do not burn “paper money”² in the designated containers provided but on public walkways. The resulting fire and debris causes obstruction and inconvenience to pedestrians while flying ash/debris can make the estate grounds untidy.

Photo 3: Neighbourhood maintenance issues (all photos from respondents)

Damaged benches in neighbourhood park not replaced

Rubbish in recycling bins, clutter not cleared

Burnt “paper money” residue in public space

Even though photo-taking is a useful method to find out what older people feel about their neighbourhood and help convey the ineffable, hard-to-put-into-words feeling, it is not without limitations. Its effectiveness depends on several extraneous factors such as who is taking the image (the person taking the photograph decides what to include/exclude and where to take it),

² Burning paper money for the dead is a religious-cultural practice, part of Chinese Taoist ancestral worship.

who is viewing the image and the context in which the image is being viewed (the photograph is open to interpretation, sometimes in ways that those taking the image might not have intended or imagined). Some people may find this research activity time-consuming, to have to follow through one whole week of continuous photo-taking, and thus, decline participation. This potentially excludes people who are busier, engaged in full-time employment, and/or with limited mobility. Furthermore, this method requires the researcher and participant to have access to a photo-taking device (smartphone or camera) as well as a process for checking and transferring daily photographs from participant to researcher. There is also the logistical challenge in scheduling the discussion session after photo-taking.

Conclusion

The photo-taking and sharing activity has proven useful for involving older people in the research process. It gives the researcher an opportunity to see the built environment through the eyes of the older users as they go about their daily travel and activity, which otherwise are not easily conveyed verbally if only using conventional interviewing (see also Glaw et al, 2017; Harper, 2002). In the process, older people become research participants of their own neighbourhoods as they take photographs and speak about their photographs in their own words. The process provides an opportunity for older people including the less educated to show and speak out about their own life experiences, concerns and ideas. Through their self-generated photographs and sharing, they are able to bring in their ideas, visualise and identify issues of interest to themselves.

In this case, they gave narration to what they liked and disliked about their neighbourhood for growing older – the green spaces, amenities, community activities and are friends with people within their neighbourhood through activities like community gardening and regular exercise. They illustrated with location and action where neighbourhood maintenance and inconsiderate behaviour of other residents could be problematic to them and the community. They made visible how solution to one problem had sometimes created unintentional problems for others.

Since the built environment is inherently experiential and visual, the inclusion of photographs accompanied by descriptions from the participants has the potential to generate and bring to the fore everyday life behaviours, ideas or social worlds that are not easily conveyed by verbal description alone or missed as mundane and unimportant. From a practical perspective, the advances and prevalence of digital technology have made this research method much easier (some help will be needed for older participants who are not familiar with photo-taking/camera use) even though it remains subjective and somewhat time-consuming.

Abstract: In the past ten years, China has ushered in a new era of urban development. The urban renewal project has gradually changed the original urban pattern. In the suburbs, the construction of new cities has replaced the old towns and formed two types—an industry-led new towns and life-oriented new towns. The Zhangjiang area is one of the earliest industrial zones in Shanghai. It is currently in an important period of transition from industrial zones to the urban area. The comprehensive improvement of scientific research capabilities, living environment and urban vitality is its development goal. The long-term industrial development has led to the relatively closed industrial parks in the Zhangjiang area. The high-end communities have been built everywhere but the supporting facilities are insufficient. This has led to the emergence of city-industry separation, and separation of jobs and residential in the Zhangjiang area. These problems are particularly prominent in the Zhongshi units. In the process of building a fast new town, Zhangjiang Old Town, which was originally water-based, gradually declined, and was replaced by a new town with roads as the development axes. Planners used modern and mature design methods to design high-end residential communities and spacious car roads, but also brought public space with no vitality. Taking the Zhongshi unit of Zhangjiang Science City as an example, this paper first analyzes the existing characteristics of public space, and takes the waterfront space as the research focus. It is found that the waterfront space is characterized by privatization and marginalization. After that, some urban design method was used to redesign the form of waterfront space, function, and relationship with the surrounding area in order to realize the reuse of the public space.

Keywords: waterfront public space; urban renewal; privatization and marginalization;
Zhangjiang Old Street

1 New town development model and existing problems

1.1 Two models of the development of China's new town

With the continuous development of China's economy, the urbanization process is also accelerating. In 2018, China's urbanization rate is close to 60%, and the city is undergoing rapid changes and transforms. In the core area of the city, the urban renewal project with the main contents of comprehensive renovation, functional change and demolition and reconstruction of existing buildings, infrastructure, public facilities, streets and environment is changing the original urban pattern (Chen, 2019). Tianzifang, Xintiandi in Shanghai and other urban traditional street reconstruction projects have become a model for urban renewal in the country. Due to the expansion of the city's scale and the need for development, there is no land and space for urban development in the city center or the old city. As a result, various new town and new district planning and construction projects have been carried out across the country to meet the needs of industrial development or urban population expansion.

New town or new district is a relatively independent unit planned for political, economic, social, ecological and cultural needs(Feng, 2015). After more than 30 years of construction, China's new town and new district has formed a huge and complex system. There are many types and development models of new urban new districts. Many new town developed from industrial parks have become important economic growth poles besides the core areas of the city. Due to the rapid development of the new town, it is also facing problems such as city-industry separation and lack of vitality. The development model of the new town needs to be transformed. The relationship between industry and urban space has always been an important issue in the development of new towns in China. The problem of city-industry separation has seriously restricted the healthy development of cities. Scholars have conducted in-depth research on the phenomenon , the classification and causes, and the path of city-industry integration. At present, China's new town and new district can be divided into four categories: residential new district, industrial park, high-speed rail new town and science and technology new town(Yang and Lin, 2017). Its development model can be classified into the following two situations.

The first is new town formed by industrial agglomeration, represented by industrial development zone. Most of the industrial development zones are located in the suburbs, relying on the construction of industrial parks to form industrial clusters, and promote the economic development of the new town. In terms of space, large-scale closed spaces such as factories and parks have gradually replaced the more densely populated old towns and farmland. People live

in places with good housing conditions and supporting facilities in the city center, and only work in the new town during the day. Second, new town relying on opportunities such as high-speed rail with the residential area is the main function. In order to share the population pressure in the city center, large residential areas are built on the edge of the city or in the suburbs. Lower prices and larger space meets the housing needs of people working in the city center. However, there are certain problems in the current two development models. The new town with industry as its main function cannot provide supporting service facilities. The new town with residential function as the main function lacks industrial support. It will be less attractive to talents, so the ability to absorb the population is limited. The space differentiation between jobs and residences causes the industrial park to become a "ghost town" at night, and the strange phase of the residential area becomes "empty town" during the day. It leads to the lack of vitality in the city and the low sense of identity of the crowd.

1.2 Development and transformation background of Zhangjiang area

Zhangjiang High-tech Zone is located in the center of Shanghai Pudong New Area, adjacent to Lujiazui Financial Center and Shanghai Disneyland (Figure 1). Since the establishment of the Zhangjiang Hi-Tech Park in 1992, it has experienced the development phase of the exploration period (1990-1999), the incubation period (2000-2005), and the development period (2006-2011), and entered a new era of transformation (Wang and Huang, 2013). After the implementation of the "Zhangjiang" policy in 1999, a large number of high-tech industries gathered in Zhangjiang. The area of the park continued to expand, and the industrial functions were further strengthened and improved. It became the vitality point of the economic development in Pudong, and its influence continued to expand. In 2011, Shanghai was approved to establish China's third national independent innovation demonstration zone, and named after Zhang Jiang. The word Zhang Jiang has become synonymous with Shanghai's high-tech development, and Zhangjiang region has entered a new era of transformation and development.

In 2017, the "Zhangjiang Science City Construction Plan" was approved (Figure 2). The plan is based on the original Zhangjiang High-tech Industrial Development Zone. The area is increased to 94 square kilometers, and a science city integrating production and urban space is to be established. With the concept of open agglomeration, integration of diversity and green communication as the planning concept, the transformation and development of Zhangjiang Science City will become the creation place of new knowledge and new technology in China and the world, the breeding place of new industry, modern new livable city and municipal public center. And built into a world-class science city.

Figure 1 Zhangjiang Science City Bitmap

Figure 2 Land Use Planning of Zhangjiang Science City Construction Planning

1.2 Main problems in the construction of new towns

Zhangjiang Science City began construction in the 1990s. Planners use advanced planning concepts and design techniques to design clean, modern and urban areas. However, in the past 30 years of, some contradictions and problems have been exposed. The livability and vitality of the new town have not met the vision of the government and planners. The Zhongshi unit is located in the north of Zhangjiang Science City. It is the earliest developed unit in Zhangjiang area. The northwest corner of the unit is an industrial park, the east is a large-scale residential area with mature and mature construction, and the southwest corner is a newly-planned software park. It presents a pattern of intertwined collages between residential areas and

industrial areas. From the perspective of the Zhongshi unit, the main problems reflected in the new town include the following aspects.

First, the industrial park area and the residential area are relatively independent and the supporting facilities are insufficient. The density of public service facilities in residential areas is enough but unevenly distributed, lacking comprehensive hospitals and cultural and sports venues. Second, the road is wide but not suitable for walking, which makes it empty. Each urban cluster has a fence, which is closed to the public. People mainly work in residential areas or work inside industrial parks. The street only bears the traffic function. Although there are walking and running lanes, there is no corresponding supporting function on both sides, and the road is too wide, the radius of the turn at the intersection is large, causing people to lack the desire to travel. Third, the ecological base is rich, but the accessibility and continuity are poor. The landscape function of the green space is greater than the public activity function, and it is not systematic. There is a fault zone in the waterfront activity space. Fourth, ignore the inheritance of historical context. The old town of Zhangjiang are damaged, the intangible cultural heritage lacks the space carrier, and the emerging culture lacks the output platform and space.

2. Introduction to the water environment of Zhangjiang Old Street

2.1 Impact of urban development on river systems

The Yangtze River Delta is a typical plain river network area. The water system of the Pudong New Area is vertical and horizontal, with a typical Jiangnan water town style. The water system and the town are interdependent. As an important part of the urban public space, the waterfront space can not only improve the urban micro-environment, but also improve the environmental quality. It is also a public place for residents' activities. In the planning of the new town, the planning of the waterfront area is a key design area to display the image of the city. The dynamic waterfront space design can drive the economic development of the surrounding area and become a symbol of the region. However, the construction of the new town is often accompanied by the destruction of the original river network. In the construction and development of the Zhangjiang High-tech Zone, in addition to the rivers or main streams in the center of the city are preserved and redesigned, many tributary water systems are landfilled into roads or the construction of the park. The original farmland was requisitioned, and the water environment of some water systems was also invaded by industrial pollution, causing the river network to shrink and the water surface rate to drop. Bai Yiqin (2010) compared the land use and water system remote sensing data and water environment quality in Pudong New Area over the years, and found that with the acceleration of urbanization process, the length, area and

quantity of river network decreased. Small and medium-sized rivers and village-level rivers disappear faster. In the central urban area, the network is relatively systematic, while the river network in the urban fringe area maintains the original natural form. (Figure 3).

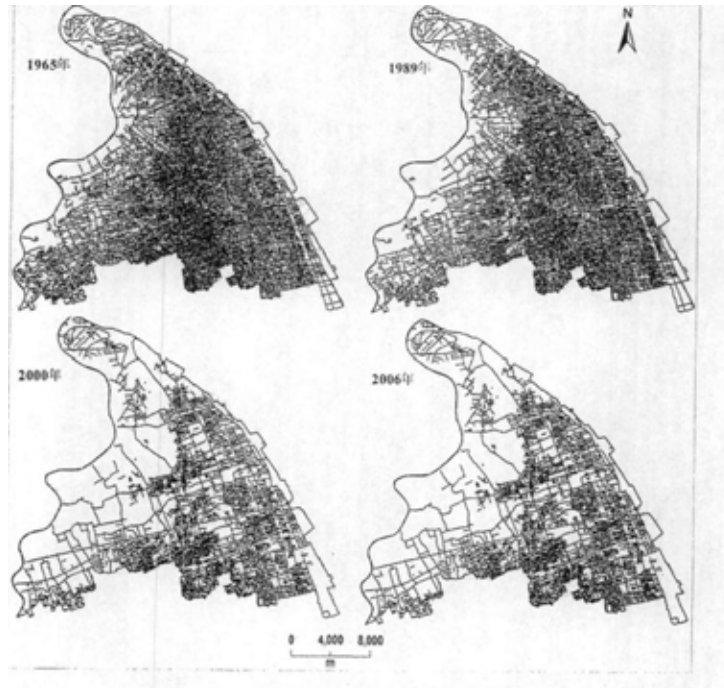

Figure 3 River network changes in Pudong New Area from 1965 to 2006(Bai, 2010)

2.2 Water resources around Zhangjiang Old Street

There are many rivers in the Zhongshi unit. The main two rivers, Majiabang River and Lvjiabang River cross in the middle of the unit (Figure 4). The river from west to east is the main traffic in the hinterland of Pudong. Transporting waterways, nowadays, has lost its transport function and has become a landscape river. The north-south Majiabang River was dilapidated and digging through the original Libang channel. In addition, there is a river called Taohe passing through the east of the unit. The river sets the Majiabang River and Lvjiabang River together in the interior of the block to form a ring structure.

Figure 4 Existing river in Zhongshi unit

The intersection of the two rivers of Majiabang River and Lvjiabang River is the location of Zhangjiang Old Street. Zhangjiang Old Street is a spontaneously formed market town formed during the Ming Dynasty (1567-1572). It retains the longest historical memory in the Zhangjiang area and the original spatial pattern of the Jiangnan water town. The old street extends along the east and west sides of Lvjiabang River, and the enclosed courtyard space is arranged in layers to form a deep spatial feature of the courtyard. A main street is set up in parallel with the water system to form a house-street-river spatial pattern. A number of lanes are perpendicular to the water system and extend to the bridgehead, the water system intersection, and the intersection to form an open space (Figure 5).

Figure 5 Zhangjiang Old Street courtyard and water street space pattern

3. The role of waterfront space in the change of Zhangjiang Old Street

Up to now, the surrounding area of Zhangjiang Old Street has been replaced by modern industrial parks and residential buildings, and the construction of new town is still in progress. Zhangjiang Old Street is also facing demolition, and some indigenous people have left their long-term residence. In the process, Lvjiabang River transformed from the original main

transportation channel into a landscape river channel, and the waterfront space was transformed from a lively and energetic public space to a place where no one cares. From a historical point of view, the change of Zhangjiang Old Street witnessed the entire process of industrial park development changing the old market town space.

3.1 Late Ming dynasty to the Republic of China: prosperous period

The history of Zhangjiang Old Street can be traced back to the Ming Dynasty. It is said that there are two phoenix trees on both sides of Lvjiabang River. Therefore, the old name is Gutongli. During the Longqing period of the Ming Dynasty, there was a man named Zhang Jiang who opened a ceremony here. He built a fence as the boundary between the east and the west, so it was named "Zhangjiangzha". At this time, the river channel is the main means of transportation. Both the cargo ship and the passenger ship to and from the sea and Shanghai have to transport each other through the rivers. As one of the main transportation waterways in the hinterland of Pudong, the Lvjiabang River has frequent commercial trade on the river. Zhangjiang Gate has also developed as a major market town along the Lvjiabang River. By the time of Qing Emperor Qianlong, Zhangjiangzha had formed a commercial market town with more than 200 shops. The number of households exceeded 1,000, and it formed a 100-meter-long east-west street and a north-south street and sugar shop across the Lvjiabang River. Street (Figure 6). By the time of the Republic of China, Zhangjiangzha was already a major town in the northern part of Nanhui County, and a water and land transportation hub, known as the "North Gate Key." Until the 1950s, Zhangjiangzha has always been a commercial and trade center in the district. The waterfront space is mainly commercial activities. The merchant ships that come and go are docked at butou for loading and unloading goods. There are many shops, tea houses and pubs on both sides. The commercial atmosphere is strong (Figure 7). It can be said that ZhangJiangzha has developed and expanded by relying on the transportation of the Lvjiabang River River. The waterfront space is the most popular public space in Zhangjiangzha, and it is also the place where people interact and trade.

Figure 6 The whole territory of Nanhui County, Qianlong, Qing Dynasty

Figure 7 Zhangjiang Old Street Historical Image (1948)

3.2 After liberation: privatization of space brought about by the transformation of functions

After the founding of New China, with the start of the economy, a large number of urban construction activities occurred frequently. Chinese cities entered a stage of rapid development. Due to the change of transportation mode, land transportation has gradually replaced water transportation and has become the main mode of transportation. A large number of roads were built, and influenced by the traffic location, commercial and other public functions began to gather on the road. In Zhangjiang, the new town center was established on the west side, and the shops concentrated on the roads, forming a pattern along the ZhenXixin Street, Chuanbei Road, and Zhangjiang Road (Figure 8). The original commercial functions of Zhangjiang Old Street were gradually replaced into living spaces. Old Street lost its status as a core city and became a town dominated by residential functions. This process is spontaneous and not government intervention. Since 2000, Guanglan Road

has been constructed, and Zhangjiang Old Street has been divided into two parts (Figure 9). The old street of Zhangjiangzha has entered a decline period. The functional changes on both sides of the river and the decline of water transport have also made the riverside space The original commercial vitality space has been transformed into a living space for residents.

With the improvement of people's quality of life requirements, the living conditions of Zhangjiang Old Town are becoming more and more crowded, and the waterfront space is showing a trend of privatization. In the period of our investigation, the aborigines have not yet fully moved out, and we can see the imprint of life that has been preserved on both sides of the river bank. Some illegally built sheds extended from the residential houses to the river banks. The fences blocked the waterfront roads. The riverside stood many poles for drying clothes, and it became the home of the residents on both sides of the river.

Figure 8 Zhangjiang Old Street Historical Image (1948)

Figure 9 Zhangjiang Old Street Historical Image (1948)

3.3 The construction period of the new town: the marginal space in the development of the new town

Since the 21st century, urban construction in Zhangjiang has entered a stage of rapid development. As mentioned above, the changes in the river system of Pudong New Area have also been staged around Zhangjiang Old Street. Now the water system around Zhangjiang Old Street faces the following problems, affecting the vitality of waterfront space.

First, the tributary water system lacks management and the waterfront space is poorly accessible. On the south of Zhangjiang Old Street, there is a river that runs through Pudong New Area and is 28 kilometers long and about 70 meters wide. It is also one of the main main streams in Pudong New Area. The city-level public service center will be built on both sides of the Chuanyang River. The implantation of science and technology and public service functions will greatly stimulate the vitality of the riverside space on both sides of the Chuanyang River. The Zhongshi unit where Zhangjiang Old Street located is in the northern part of Science City. Its status and role are much lower than those on the banks of the Chuanyang River. The tributary water system such as Majiabang River is neglected, the river channel is narrow, and some riverside landscapes are poor and lack of management. In addition, due to the complex property rights on both sides of the Lujiayu River and the Majiabu River, the public shoreline has not been integrated into unified management and planning. Most of the shorelines are in a closed management mode and are not open to the public (Figure 10). Besides, the collapse of many river-crossing bridges has not been repaired (Fig. 11). The river banks are filled with domestic garbage and building materials, so the connectivity and accessibility of the riverside space is poor (Figure 12). This is also one of the main reasons for the openness and vitality of the riverside space.

Figure 10 Waterfront space with closed management measures

Figure 11 Bridge collapse

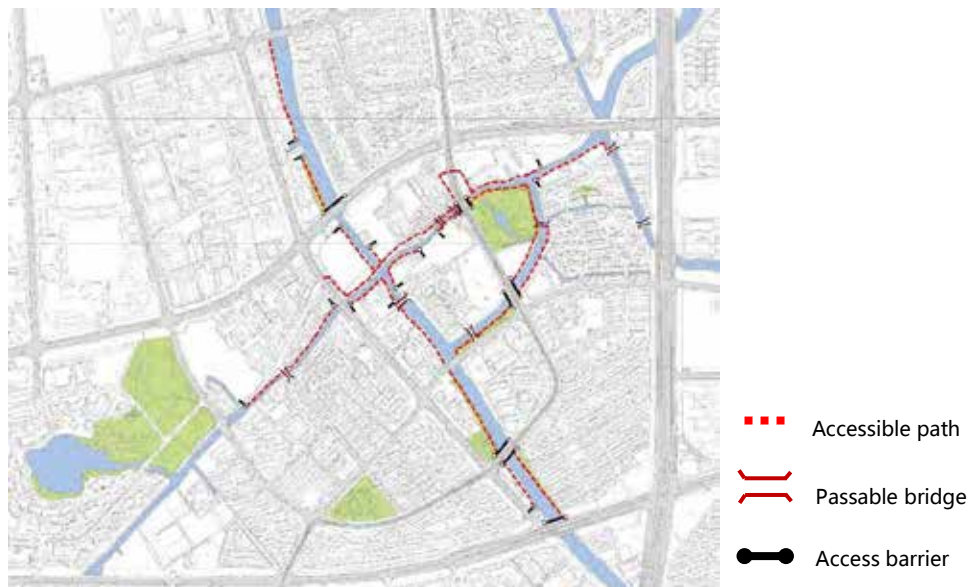

Figure 12 Analysis of the Traffic Situation between Ma Jiazhen and Lu Jiayu

Second, the river bank line is simple and lacks design, and the waterfront space is difficult to get close. Take the Majiabang River River passing through Zhangjiang Old Street as an example. The south side of the eastern section of the river is Guanglan Park. Combined with the streamline design of the park, the walkway and the hydrophilic square are set up in the waterfront space, and the space is relatively open. On the other side of the Guanglan Park, the embankment is relatively simple, with fences as the mainstay. Although the passage space of the old street waterfront was preserved, it was undesignated and the vegetation was overgrown, which made it impossible to get close. In the important urban core area, the waterfront area is a place where vitality gathers. But in the non-core area such as Zhangjiang Old Street, the waterfront space exists only as the “back of the street”, and the waterfront space is neglected and becomes the edge of the city. (Figure13, Figure 14).

Figure 13 The difference between the two sides of the Majiabang River River is obvious

Figure 14 Straight shoreline with vegetation

4. Design strategies of waterfront space: reuse and vitality

In order to preserve the spatial pattern of the water town of Zhangjiang Old Street and enhance the vitality of the waterfront space, we designed the area around the cross-shaped river formed by the Lujiayu River and the Majiabang River River, covering an area of about 33 hectares. A design response strategy is proposed for the waterfront space. The land includes Zhangjiang Old Street and some Zhangjiang Townships built after the 1990s. Existing buildings are dominated by industrial, residential and businesses. It is hoped that through the planning of space design techniques and theme functions, the waterfront space of Zhangjiang Old Street will be activated, thus driving the regeneration and development of the entire area.

4.1 Public function is concentrated in the river

Science and technology is the eternal theme of the development of Zhangjiang area. In the vicinity of the design scope, there are software parks based on R&D and innovation, as well as industrial parks that focus on parts processing and manufacturing and have future transformation and upgrading needs. However, there is a lack of places around the base for R&D personnel to rest and exercise. In addition, the surrounding cultural atmosphere is relatively strong. Zhangjiang Drama Valley, Zhangjiang 368 Cultural Industrial Park and

Changtai International Cultural Center are located in the Zhongshi unit, but these cultural industries lack a platform for export and publicity, resulting in insufficient influence. Therefore, we consider implanting technological innovation and cultural creativity related functions in the base to gather public functions to the river. The waterfront space serves as a space carrier for the external display and activities of the creative experience function, and promotes the regeneration of the riverside space with diversified functions.

Create a common core of science and technology at the intersection of rivers. The Chuangzhi Square, the Game Interactive Hall, the Comprehensive Experience Hall, and the Binhe Park are arranged around the river intersection to form a public activity center. The Chuangzhi Square on the west side is the main place for undertaking various kinds of performances. It is also a place for residents and researchers to exchange and gather. In combination with the outdoor space of the Exhibition Center, various technology product launches, creative markets and roadshows can be held. It is also a great place for watching the waterfront landscape. The north and south sides are equipped with small-scale buildings, which is a continuation of the old street texture. They allow small and micro enterprises to interact and experience offline and attract people. On the east side, a riverside park was designed as the most concentrated public space in the entire area, allowing busy people to relax and enjoy the natural beauty after work.

On the east side of the science and technology public core is the reserved Zhangjiang Old Street area, along the river to form a waterfront business district based on casual dining, and join the retail, experience, old street memory hall and other functions. Further to the east is the commercial service and leisure area formed by the Guanglan Road subway station. While continuing the function of the old street, it also adds functions such as parent-child activities, shopping and entertainment, and provides corresponding supporting facilities for the surrounding communities. On the west side of the science and technology public core, the current building quality is good. The main problem is that many closed blocks are formed due to the barrier of the wall, and there are more negative spaces. Therefore, the micro-update method is adopted to sort out the stock space, and the waterfront landscape is infiltrated into the area, and sports activities facilities and leisure plazas are arranged in places with large space as places for residents' activities.

Three theme routes are planned, which are the Old Street Discovery Tour, the Kechuang Experience Tour, and the Leisure and Recreation Tour. The public nodes besides River are connected in series to create a communication place (Figure 15).

Figure 15 Theme tours and public events

4.2 Reconstructed River Street Space

Due to the acceleration of the construction of the new town, the original river street space of Zhangjiang Old Street has been destroyed, and the modern waterfront space is obviously not suitable for this historic land. By combing the existing architecture and space texture, we summarize the past river-street relationship of Zhangjiang Old Town based on historical images, hoping to rebuild the river street space and continue the traditional space pattern of the old street. According to the existing building quality, the buildings that need to be demolished and can be reconstructed are selected, and new buildings are implanted to bury the damaged space. The original space texture of the old street is restored and continued. Some of the waterfront space design direct waterfront commercial interface, enhance the accessibility of the waterfront space, and form a continuous pedestrian street on both sides of the river bank. Thus, a building-street-river-street-building spatial relationship is rebuilt(Figure 16). The bridgehead is designed with a relatively small open square to form a small public node in the neighborhood. The riverside combines commercial buildings to form a good leisure and commercial space. The outdoor teahouse and viewing platform are set up to reshape the traditional watertown atmosphere.

Figure 16 Spatial relationship of river and street in Zhangjiang Old Street

4.3 Shoreline design for different people and functions

The waterfront space adopts a differentiated design approach to the functions of both sides of the river to create a variety of waterfront space forms and meet the needs of different groups of people. The shoreline can be divided into four sections according to its functions: the living section on the west side, the river intersection section, the Zhangjiang Old Street section, and the Guanglan Park section.

The living section on the west side: the riverside is dominated by talent apartments, commercial and residential areas, and the living atmosphere is strong. The riverside creates a community atmosphere and increases the space for residents to do some activities. The original single straight shoreline is partially widened to form a multi-layer retreat, and a continuous two-story water walkway is provided in combination with the two sides to provide a venue for fitness, leisure, and community activities (Figure 17, Figure 19).

Figure 17 Waterfront perspective of the living section on the west side

The river intersection section: At the intersection of the two main rivers-Majiabang River and Lvjiabang River, it is the most crowded place for crowds. Therefore, it is necessary to design a shoreline with a high degree of publicity to provide outdoor activities and make full use of the waterfront. The landscape creates a vibrant and open atmosphere. Design a shoreline form that is open to the surface of the water, and maximize the provision of a hydrophilic space by adding sunken plazas, waterfront terraces, and stepped slopes. Part of the waterfront building has a roof garden that provides a rich view space in the vertical direction (Figure 18, Figure 20).

Figure 18 Waterfront perspective of the river intersection section

Figure 19 River section of the living section on the west side

Figure 20 River section of the river intersection section

Zhangjiang Old Street section: There are many commercial buildings on both sides of the old street, and the shoreline has been redesigned. When the street is indirectly facing the river, it is completely open space. When the building is directly facing the water, the street is a semi-open space on the inside and becomes the backyard of the waterfront shop. The two ancient bridges, Zhong'an Bridge and Taiping Bridge, are restored, and the landscape and the directly hydrophilic steamed buns are intertwined to form an ecological and artificial mixed coastline. The traditional waterfront forms such as Shantou, plank road and wooden bridge are used to

link the waterfront street with the Lvjiabang River. The riverside space occupied by the residents is designed to open to the public, forming multiple riverside parking spaces and reshaping the atmosphere of Zhangjiang Old Street. (Figure 21).

Guanglan Park section: The south bank of the Majiabang River on the east is Guanglan Park. The landscape resources are good and the flow of people is dense. It is in stark contrast with the landscape on the north bank. The waterfront space between the two sides lacks contact. Design a waterfront revetment that is partially open to the river and form a contrast with Guanglan Park. The tour line in Guanglan Park is also close to the river. The hydrophilic platform is added to the narrow river. People can directly enter Guanglan Park from the north side, which also enhances the accessibility of Guanglan Park and the radiation capacity to the surrounding area. (Figure 22).

Figure 21 River section of Zhangjiang Old Street Section

Figure 22 River section of Guanglan Park section

4.4 Pay attention to walking space

The entire area requires people-oriented, paying attention to the walking experience and weakening traffic. The internal roads are dominated by narrow urban roads, and landscape and lifestyle roads are preferred. The two main rivers are the main open space streamlines, extending the public corridors, connecting the Guanglan Park and the Zhangjiang Theme Park on both sides, and infiltrating into the surrounding areas to increase access to the waterfront space to form a public space network(Figure 23).

Figure 23 Walking space system

5 Conclusion

Zhangjiang Science City is an outstanding representative of the construction of Shanghai new town, but there is still a phenomenon of low vitality in the north, and there are problems such as insufficient supporting facilities, lack of street life, unused waterfront space, and destruction of cultural memory. This reflects the lack of humanistic care and quality in the planning and construction of the new town. Zhangjiang Old Street bears a long history of Zhangjiang area, and the change of its waterfront space reflects the change of urban construction to the spatial pattern of old towns. Through field research, we found that the waterfront space in the Zhangjiang Old Street area currently has problems such as poor accessibility and simple bank line, which leads to the lack of waterfront space vitality. In view of the above problems, we proposes a redesign of the waterfront space with four strategies as follows: public functions to be concentrated in the river, shoreline design for different people and functions, and pay attention to walking space. We hope it can activate the entire Zhangjiang Old Street and even the Zhongshi unit.

Abstract: The shallow mountain area refers to the transitional area between the city and the mountainous area. The geographical environment of Beijing has created a large number of shallow mountain areas. As a potential resource for future urban space expansion, the protection and utilization of the shallow mountain area has attracted much attention in the context of rapid urban expansion. This paper discusses the green space network planning of the Wulituo area in Beijing and the green space design of the Xishan military community. From the green network construction and the green renewal of the shallow mountain community, the green space construction strategy research of the urban shallow mountain area is carried out at the meso and micro scales.

Keywords: Shallow mountain area; Green space; Mesoscale and Microscopic scale; GIS;

Introduction

“Shallow mountainous areas” appeared earlier in China, and many scholars have carried out research and discussion on this. However, due to the large differences in shallow areas in different areas, the definition and division of shallow mountain areas are still relatively vague. According to previous studies, the overall definition is as follows: “The shallow mountainous area is part of the mountainous area. It is a certain altitude and slope of the plain. The mountainous area is a plain, mountainous and mountainous with low mountains, hills, terraces, mountain plains and alluvial fans. The transition zone between the two, and the artificial development and construction of the natural habitat of the mountain, the buffer zone.” (Feng, 2008) China's planning studies on shallow mountainous areas have focused on agriculture and forestry production in the early stage. As the ecological environment has been destroyed, the ecological environment in shallow mountainous areas has become more and more concerned. At the same time, in the face of the outward expansion of the city and economic development, discussions on the development and utilization of shallow mountain areas began to increase, but there is still a lack of planning research and specific practices. This paper takes the Wulituo area in Beijing as the research object. By summarizing the real problems in the Wulituo area and combing the development history of the area, this paper proposes the green space network construction strategy and the micro-scale landscape renewal strategy under the mesoscale scale of Shanshui City. Provide reference for the green space planning and design of the vast shallow mountain areas.

The Historical Origin and Realistic Dilemma of Wulituo Area

The Wulituo area is located in the Shijingshan District of Beijing, bordering the Mentougou District, west of the Western Hill of Beijing, and the Yongding River passes through the southwest. It is a bowl-shaped area surrounded by mountains and water, including shallow mountains and plains in front of the mountains. Through a summary analysis of the distribution of unincorporated villages in the history of Wulituo, it is found that in the natural geographical environment where the mountains, plains and river valleys are stepped and laterally distributed, the Wulituo area has developed from ancient times and its social production and living mode and settlements are closely related to the natural geographical environment. (Figure 1) Since the Ming Dynasty, many nobles have set up family cemeteries in Wulituo, established temples, and formed natural villages, such as Longen Temple Village and Shuangquan Temple Village, which are mainly engaged in agriculture, forestry and animal husbandry. In the plains, the Jingxi Ancient Road has passed through this, and the economic prosperity brought about it has formed a natural village such as Sanjiadian Village as a trans-shipment hub for coal and leather goods in Beijing. The sediment brought by the Yongding River formed suitable land for cultivation along the river, and gradually formed some natural villages.

Figure 1. Distribution Map of Unincorporated Villages in Wulituo Area. Diagram by the authors.

However, since the modern era, the Wulituo area has gathered industrial enterprises such as Xishan Machinery Plant and Shijingshan Thermal Power Plant. With the rise and fading of industry, many large industrial sites and structures have left the urban space. The abandoned railway has blocked the vertical traffic connection of the city, and the ecological environment of the area has been destroyed, and the development has lagged behind. Since the Ming and Qing Dynasties, the civil construction of Beijing City and the destruction of modern warfare have caused the original mountain forest vegetation in the Wulituo area to disappear basically, and the soil erosion is serious. In addition, the extensive expansion of the city continues to occupy the space originally belonging to the mountains and rivers. The predicament of the green space in the Wulituo area is:

- The forest is mottled and broken
- Water system and historical context are interrupted
- The passage from the mountain to the water is interrupted
- The conflict between mountains, water and cities

The Green Network Planning of the Integration of Mountain, Water and City in Wulituo Area

Based on the study of superior planning, three kinds of key words of green network planning in Wulituo area were extracted: ecology, countryside and green corridor; ancient roads, culture, leisure and recreation; development, transformation and comprehensive services. Based on this, it puts forward the planning objectives of restoring green shallow mountain forest land, finding source and waterfront context, ensuring ecological security, and connecting life and nature. The green space of Wulituo area is positioned as a transition space of landscape city integrating natural ecological conservation, original protection of rural areas, sightseeing of landscape scenery, historical and cultural inheritance, and urban life service, with shallow mountain forest land and yongding river water vein as the background, ecological security as the basis, and life connection as the pursuit.

Construction Strategy of Green Network in Wulituo Area

The construction of the green network in Wulituo area firstly analyzes the ecological security pattern of the region and the needs of urban residents' life recreation, from hydrological safety, geological safety, bio-safety, and urban parks, mountain recreation, and slow-moving demand. Through the use of GIS software and analytic hierarchy process. By constructing an ecological security pattern and a living recreation network, the initial scope of the urban green space is obtained. In addition, combined with the functional layout of other urban land, functional planning and positioning of each green space was carried out to achieve the design goal of building a green space network that meets the needs of ecological security and living recreation.

Ecological Security Pattern Construction

Through the use of GIS analysis, the basic data and literature data are used to construct the hydrological safety pattern, geological disaster buffer safety pattern and comprehensive bio-safety pattern in Wulituo area. These three patterns correspond to the water conservation area, the mountain key conservation area, the substrate, and the plaque. Blocks and corridors. A comprehensive analysis of the three patterns can provide an integrated ecological security pattern, that is, a green space based on ecological security. (Figure 2)

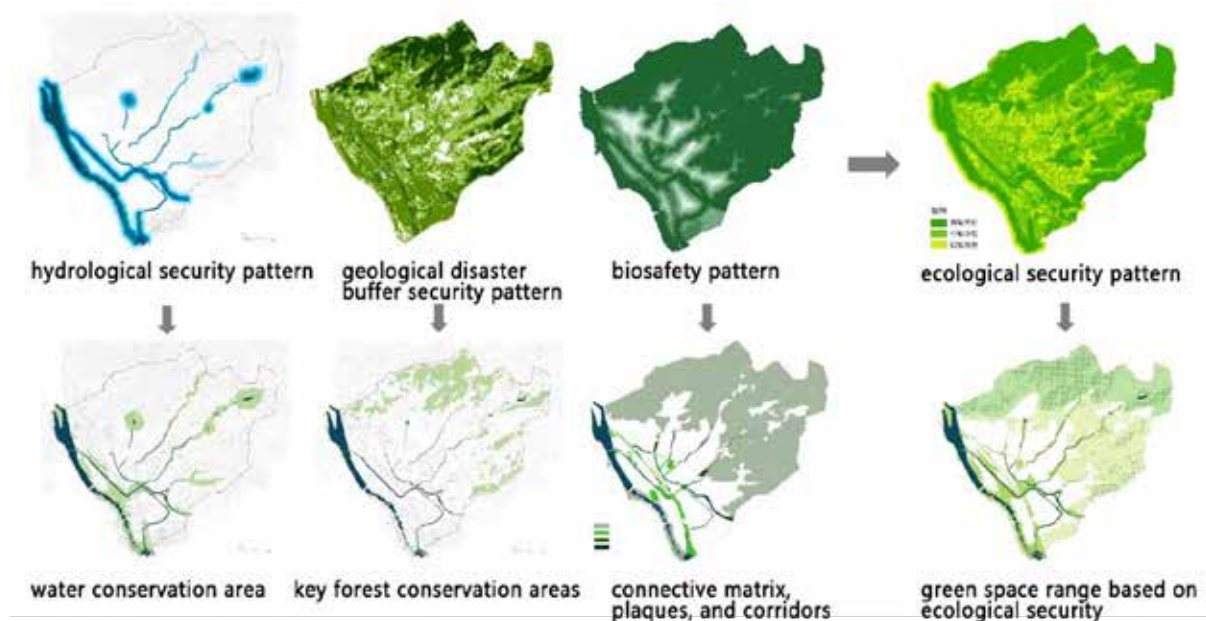

Figure 2. Ecological Security Pattern Construction Process. Diagram by Hu, E., Sun, Y., Huang, T.

Hydrological Security Pattern

Hydrology is closely related to human production and life, habitats of animals and plants, and is an important reference for flood control, drought relief, water resources management and related infrastructure construction. The shallow mountainous area is at the foot of the mountain. The mountain rainwater runoff flows from the upper part of the mountain. When it supplements the water source for the mountain river, it also forms a flash flood hazard in the rainy season, as well as soil erosion and water pollution. According to the hydrological process associated with green space, the hydrological security pattern is divided into three aspects: water conservation, rainwater defense and water quality protection. Through GIS analysis, the water source safety pattern, rain flood inundation area and water quality protection pattern were obtained, and they were superimposed to obtain a hydrological safety pattern.

Geological Disaster Buffer Security Pattern

As a transitional zone between mountains and plains, shallow mountainous areas are geological disaster-prone areas, and green space can be an important area for buffering geological disasters. Therefore, to construct a geological disaster buffer security pattern, on the one hand, it can prohibit urban construction by defining geological disaster sensitive areas as green space, and on the other hand, it can increase green space in areas with high geological disasters, thereby preventing and delaying the occurrence of geological disasters. Through the analysis of geological hazard in GIS, several factors (slope, land type, vegetation coverage) that affect the geological disaster buffer can be inlaid and reclassified according to the empirical weights, and the regional geological disaster buffer pattern is obtained.

Biosafety Pattern

The green space is an ideal habitat for a large number of living things. The shallow mountainous area is located in the interlaced zone between the mountainous area and the plain. The species richness is high, but it is also a region that is greatly disturbed by humans. The fragmentation and homogenization of the green space is unfavorable for the safety of the species habitat. Therefore, it is necessary to construct a biosafety pattern. By referring to the literature, three representative birds, mammals and amphibians in the Wulituo area were selected as indicator species. Based on their living habits, the impact of species and other factors on species movement

was scored. Then, based on the island biogeography theory, the biological source area is selected, the landscape resistance surface is established, and the spatial analysis is carried out by GIS to identify the buffer zone, the source connection, the radiation channel and the strategic point, and the safety patterns of the three species are superimposed to construct a comprehensive biosafety security pattern. Different levels of safety were visualized and graded to form a comprehensive assessment of habitat suitability of the three species. Then it is superimposed with the analysis of vegetation coverage to obtain a comprehensive biosafety pattern.

Life Recreation Network Construction

The urban green space is responsible for important life recreation functions. By defining the urban residents' demand for urban park green space in Wulituo area, the park system is constructed, the mountain forest area with recreation value is demarcated, and the chronic demand integration slow-moving system of the population in the area is analyzed, and then the construction of the living recreation network is completed. (Figure 3)

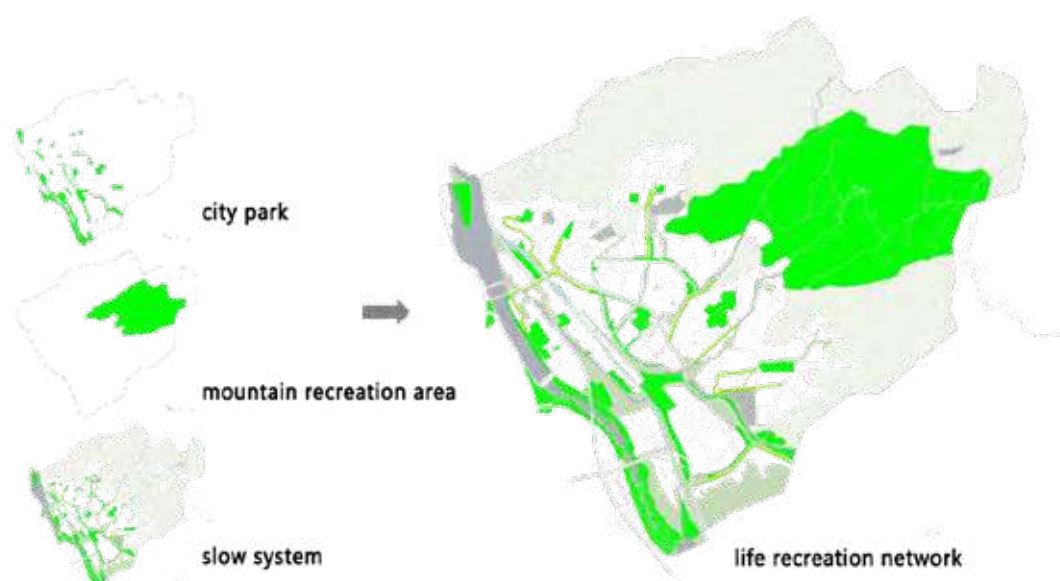

Figure 3. Life Recreation Network Construction Process. Diagram by Zhao, X. and Fan, B.

City Park

According to the Ministry of Housing and Urban-Rural Development, the park service radius of 500m should cover all residential areas. The coverage of the park green space with an area of more than 5,000 square meters in the Wulituo area has not yet reached this standard, and it is necessary to increase the urban park in the blank area. Through the renewal of urban wasteland and the renovation of existing green space, covered the blank area by the park service, new urban parks will be planned according to the current conditions of the plot and the principle of uniformity. The urban park's 500m service radius covers all urban residential areas, and meets the urban park needs of residents in the Wulituo area in terms of spatial layout.

Mountain Recreation Area

The demarcation of the mountain recreation space is mainly based on the analysis and evaluation results of the ecological sensitivity assessment and the mountain recreation demand analysis (mountain landscape value and humanistic features). Areas with high ecological sensitivity are not suitable for recreational activities, and areas with high demand for mountain recreation should be included in the mountain recreation space for demand. The range of mountain recreation areas is comprehensively defined by the ridge line and the road.

Slow System

The construction of the slow-moving system begins with the selection of various types of slow-moving needs. By crawling out the commercial hotspots in the area with big data in the Internet, it combines residential areas, urban parks, cultural relics, public transportation stations, and riverside landscape nodes. These points are connected and selected, and the results of urban greenway selection are obtained after comprehensive superposition and partial adjustment. The mountainous area is rich in mountainous recreation resources, and the construction of mountain forest recreation trails is indispensable. According to the walking trajectory of the hiker recorded from the track record app, the potential route of the mountain recreation and the viewpoints along the line are obtained. Combining the existing mountain roads, we can obtain the results of the selection of our mountain trails by retaining, adding, connecting, and extending these routes.

Construction of Green Network in Wulituo Area

By superimposing the green space based on ecological security and life recreation, combined with the current satellite imagery, the planned green space is obtained. Considering the natural ecological factors of green space and the surrounding areas of commercial, residential and educational land, the dominant and composite functions of green space are determined. Eventually, a green space network linking mountains, rivers and cities will be formed.

Green Landscape Renewal of Xishan Military Industry Community in Wulituo Area

Xishan Military Industry Community, located in the hinterland of Wulituo, mainly includes the factory area and family area of Beijing Xishan Machinery Factory, one of the former “Eight Factory in Western of Beijing”. In recent years, production in the factory has stagnated, community infrastructure has been slow to update, and the needs of residents' living and leisure have not been met. At the same time, the community located on the Tiantai Mountain is rich in mountain woodland resources, which is a valuable landscape resource for the city. Combined with the positioning of the green space in the green space network planning, the micro-scale design strategy continues the principle of meeting the ecological and recreational functions of the green space in the shallow mountainous area. At the same time, in close connection with the actual situation of the site, the design method of landscape garden was used to respond to the problem of urban renewal. (Figure 4)

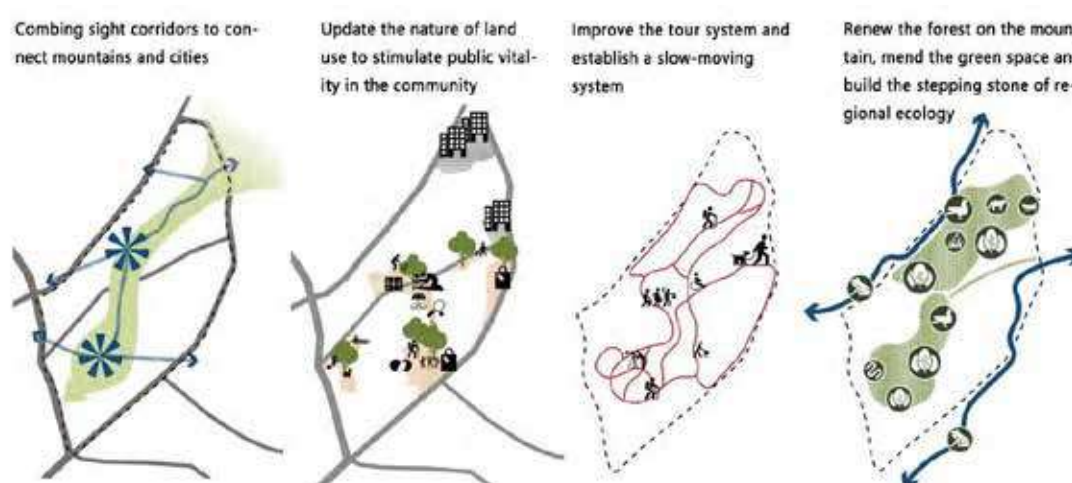

Figure 4. Design Strategy. Diagram by the authors.

Combing Sight Corridors to Connect Mountains and Cities

By dismantling the existing shantytowns and shops to expose the mountain and opening up the sight window and sight corridor for the tourists at the entrance of the park, the different styles of the mountain parks are

shaped, and the demand for “seeing” from the urban interface to the mountain park is basically realized. By using plants to strengthen the ups and downs of mountain parks, the beautiful urban landscape is constructed. Various viewing platforms have been set up at different altitudes using different platforms. The landscape space along the way of the mountaineering makes up the landscape sequence with the open space under the mountain, the enclosed space on the mountainside and the open space on the top of the mountain.

Update the Nature of Land Use to Stimulate Public Vitality in the Community

Within the design scope, there are large-scale shantytowns, low-end businesses, and messy wasteland. After identification and evaluation, three shanty towns and low-end businesses were demolished. In combination with the overall lack of commerce in the Wulituo area and the potential commercial needs of large residential areas in the surrounding areas, large commercial centers and commercial pedestrian streets will be established to stimulate regional vitality. Located in the center of the military community's residential area, there is a community of medical service stations, community pension centers, vegetable markets, supermarkets and other community service facilities. The functions are preserved and integrated in place to form a higher quality community service center. The launched land is used as a community sports venue to build a vitality center that meets the needs of residents. The Xishan Machinery Factory site, which has basically stopped production, has been renovated and remodeled. In view of the presence of artist studios in the factory area, the factory area has been transformed into an art district, attracting artists and design groups to come here. (Figure 5)

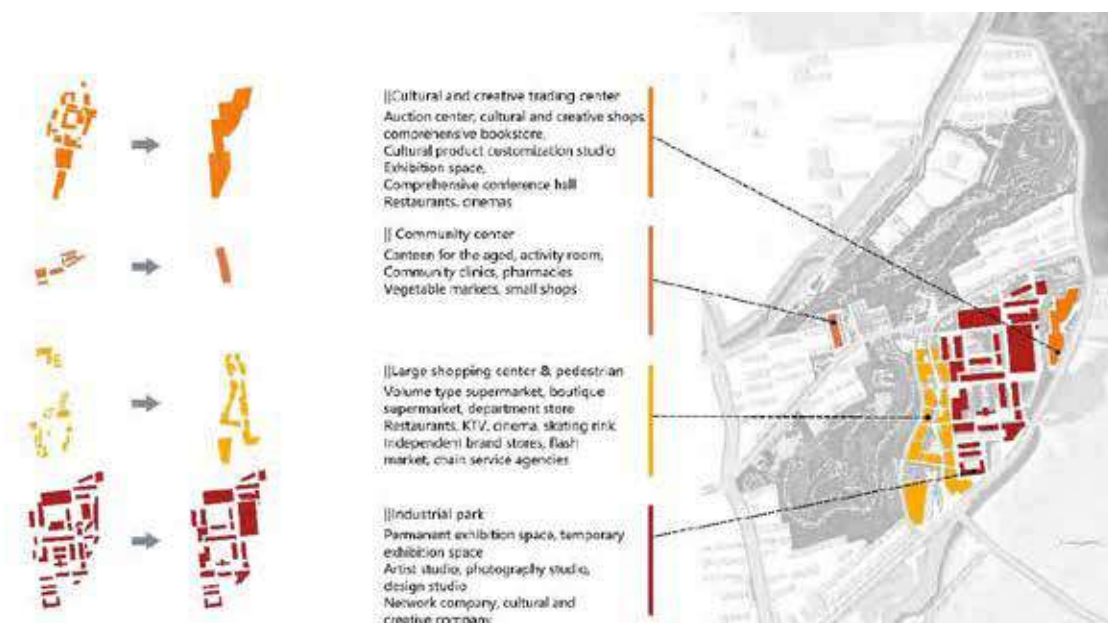

Figure 5. Land Use Update. Diagram by the authors.

Improve the Tour System and Establish a Slow-moving System

Connect the urban slow-moving roads within the designed range, suspend the slow-moving system of urban and mountainous and water systems, and form a landscape tour system consisting of mountain park roads, urban road walkways, community slow-moving systems and outdoor activity venues, and The slow-moving system in the green space network of the Wulituo area is docked. The terrain in the shallow mountain area is richly varied. By properly handling the height difference, setting up the site and carrying out special activities, it can increase the interest of slowness while satisfying the demand for traffic. (Figure 6)

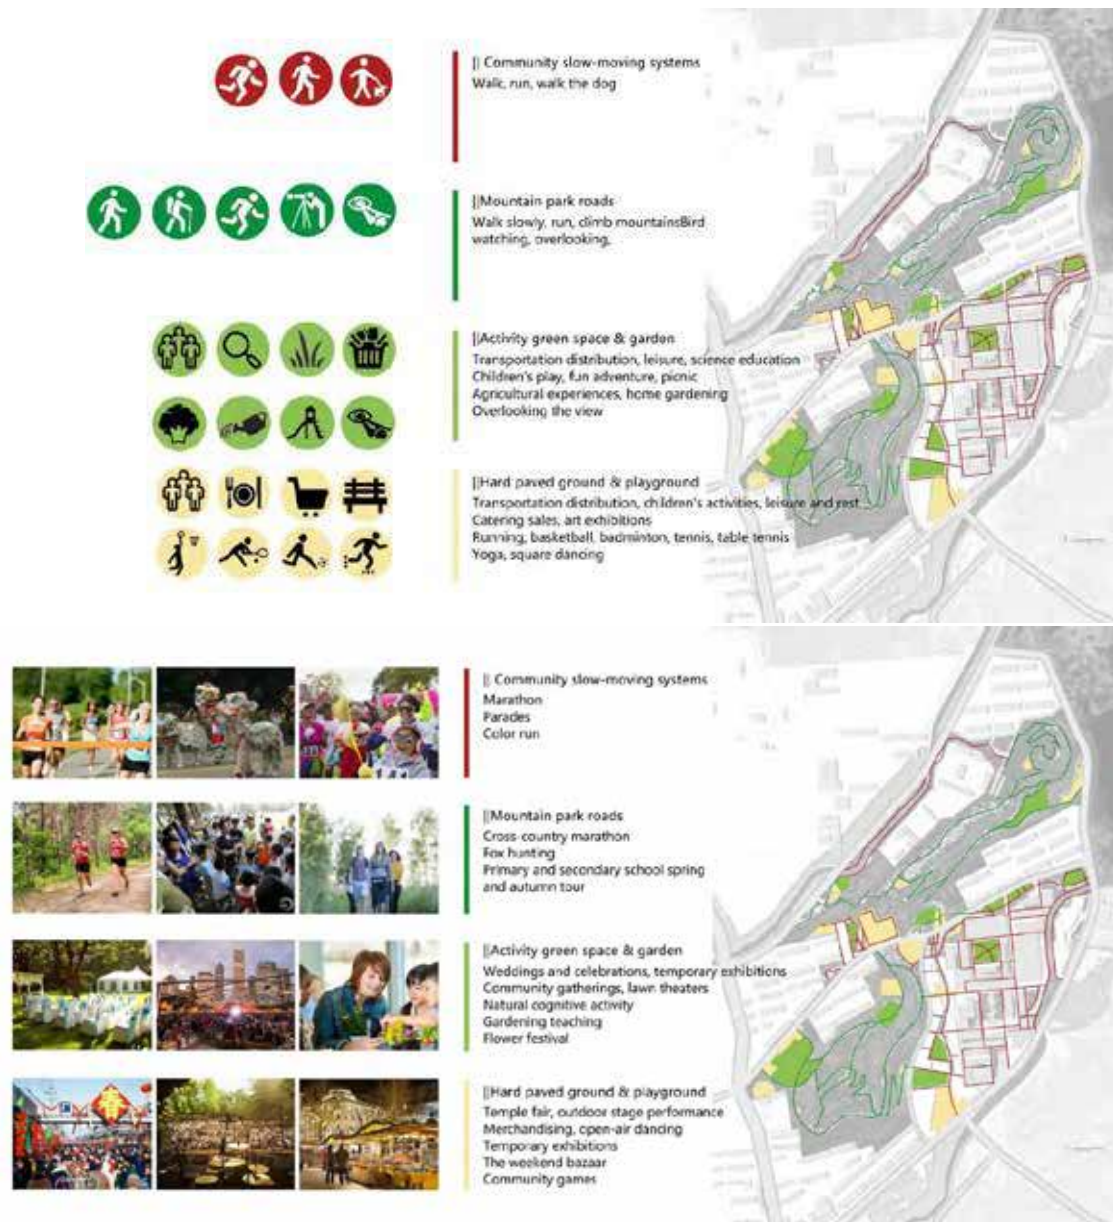

Figure 6. Landscape Slow System and Event Planning. Diagram by the authors.

Renew the forest on the Mountain, Mend the Green Space and Build the Stepping Stone of Regional Ecology

The forests in the mountains of Wulituo area are dominated by the pure forests of *Arboreal cypress* and *Pinus tabulaeaus*, which are basically the products of the artificial afforestation movement in the 1950s and 1960s. For many years, the agricultural forest management mode has been adopted to form a single-layer forest structure, and problems such as slow growth of stands, decline of soil fertility, decrease of landscape recreation function, and sharp decrease of biodiversity have emerged. (Ning *et al.* 2009) The strategy is mainly to transform the artificial forest into natural one. By hygienic cutting, removing interfering trees, adjusting the competition

between trees and the utilization of resources to promote the growth and development of outstanding individuals in the main forest layer. At the same time, through the protection and promotion of natural regeneration under the forest, and artificial replanting of the local climax community tree species -- *Quercus variabilis* -- in areas with weak natural regeneration ability, the forest recovery and self-development mechanism can be promoted. (Figure 7)

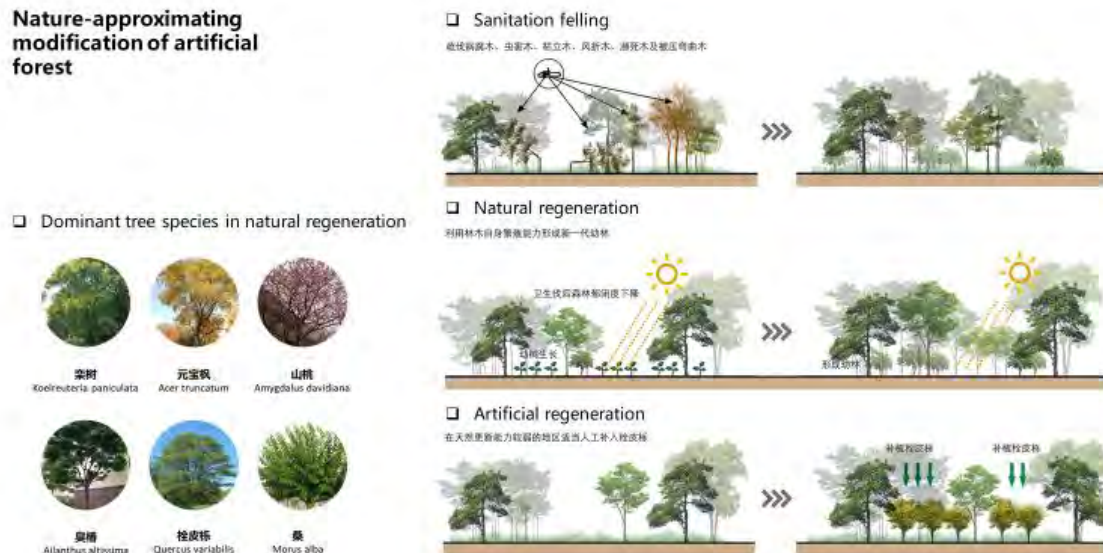

Figure 7. Nature-approximating Modification of Artificial Forest. Diagram by the authors.

The “stepping stone” refers to a small plaque habitat that can temporarily inhabit (stepping) when the animal migrates and spreads. Its presence is conducive to increasing the connectivity of the landscape, thereby increasing the chances of successful species movement and diffusion. (Hua, Li and Gao, 2005(04):30-31) The Paochang Mountain in the Xishan Military Industry Community is embedded in the city as the remaining vein of the Tiantai Mountain. Due to the good vegetation, a large number of birds are inhabited here, so the Paochang Mountain has become an ecological stepping stone. potential. In order to improve the richness of the habitat of the Paochang Mountain, the habit characteristics of the birds in Beijing woodland were considered in the selection of plant species, and the plant community was designed to meet the habitat preference of birds distributed at different heights of the plant community and provide food sources.

Renewal Results

Through the renewal of the green landscape of the Xishan Military Industry Community, it has become a region where mountains and waters are integrated, which has inspired the vitality of the Xishan military community and surrounding areas. The ecological restoration and development of the Paochang Mountain has created a new important landscape node for the Wulituo area, enriching the urban landscape and improving the construction of the urban ecological corridor. Through the reuse of stock space such as shantytowns, multiple urban functions are implanted in these spaces to provide the possibility of activating the site. In the micro-scale, the strategic principle of the meso-planning is continued, and landscape architecture methods were used to respond to the site problem. (Figure 8)

Figure 8. Updated Plan of Xishan Military Industry Community. Diagram by the authors.

Conclusions

The protection and development of green space in shallow mountainous areas is an important way to establish a balance between urban development and environmental protection. In this paper, the construction of green space at the two levels of mesoscopic network and micro-design in Wulituo district of Beijing is taken as the entry point, hoping to provide reference for rational utilization and protection of green space in shallow mountainous areas of Beijing and other cities in the world.

Acknowledgements

First of all, we would like to thank our tutors Qing Lin and Xiangrong Wang, as well as the instructors of the graduate landscape architecture design course of Beijing Forestry University. We also want to thank our Ersi Hu, Jianing Yu, Sun Yue, Baiqing Fan, Tingting Huang, without their efforts, we can not complete the overall planning of Wulituo area green space network.

Abstract: In 2016, The New Urban Agenda adopted in Quito recognized the persistence of multiple forms of poverty, increasing inequalities and environmental degradation as the greatest obstacles to the sustainable development of cities around the world.

In this paper, it is argued that, to begin to address these challenges, it is necessary to transform the formative itineraries of the disciplines linked to the production of the city. Likewise, it advocates the incorporation of socio-spatial justice and environmental sustainability as fundamental approaches into their curricula in order to respond effectively to the challenges of cities in the 21st century. In this sense, this work presents an innovative action-research-learning initiative to incorporate the socio-spatial justice approach in the context of urban planning education.

A review of theoretical approaches has been done in relation to the role of the university in the promotion of socio-spatial justice, from which an analytical framework has been developed. This analytical framework is applied to a innovative challenge-driven practices in Brazil. The research shows the actions carried out from the university in order to make visible the difficulties as well as the capacities of a community excluded from making their rights effective. Throughout these experiences, the importance of the co-production of knowledge (as a result of a collaborative work between the university and vulnerable communities) is shown, as well as the need for the university to put training and research activities at the service of society and, in particular, of social justice and not of other interests.

Keywords: Urban education and research, innovation, learning processes, social inclusion, international dialogue.

Introduction

All accepted By 2050, the world's urban population is expected to nearly double. This will pose enormous challenges in terms of access to housing, infrastructure, basic services, natural resources, etc. (UN, 2017: Section 2). Heads of State and Government, who have ratified the New Urban Agenda, recognize that the persistence of multiple forms of poverty, growing inequalities and environmental degradation will be the greatest obstacles to sustainable development worldwide (UN, 2017: Section 3). In view of this perspective, the "right to the city" is clearly included for the first time in an international agenda, as well as some of its key elements such as: the recognition and guarantee of all human rights; the social function of land; public control of speculation and gentrification processes; prevention of evictions and the fight against homelessness, and a wide range of access to housing and public services, including social production of habitat as well as other collaborative and cooperative models.

Nevertheless, it would be too naïf to think that the inclusion of these issues in the international agenda is a sufficient condition for their implementation. Many of these values and commitments have been collected for more than 40 years, from the Vancouver Declaration (1976) to the Habitat Agenda (1996) or some international declarations (ECE, 2013, 2015). Despite so many promises, the situation of human settlements around the world has only deteriorated dramatically (Pascual, 2016). According to the World Charter on the Right to the City (2004), this is because the development models implemented in most countries, both in the North and in the South, have been characterized by establishing patterns of concentration of power and income. These patterns have generated poverty and exclusion, and have contributing to environmental degradation and to the acceleration of migratory processes and socially and spatially segregated urbanization.

For decades, a paradigm shifts in the way of producing and understanding cities has been demanded. The dominant model of unlimited economic development, which is repeated as a mantra on numerous occasions in the New Urban Agenda, is incompatible with social justice and with the limits of growth of the planet (Zarate, 2017). Numerous social organizations and some local governments around the world consider *"the right to the city"* as an instrument for paradigm change insofar as it claims the city as a collective right and not as a commodity for the benefit of a few (Lefebvre 1969, Harvey 2012, Pascual, 2016, Zarate, 2017). The Right to the City would be determined, according to the World Charter of the Right to the City (2004) by three fundamental principles:

Full exercise of citizenship, understood as the realization of all human rights and fundamental freedoms, ensuring the dignity and collective well-being of the inhabitants of the city in conditions of equality and justice, as well as full respect for production and management Social habitat.

Democratic management of the city, understood as the control and participation of society, through direct and representative forms, in the planning and governance of cities, prioritizing the strengthening and autonomy of local public administrations and popular organizations.

Social function of property and of the city, understood as the prevalence, in the formulation and implementation of urban policies, of common interest over individual property rights; Implies the socially just and environmentally sustainable use of urban space.

The right to the city is a call to overcoming the prevailing model *"the right to the city is like a cry and a demand, a transformed and renewed right to urban life"* (Lefebvre, 1996: 158). It is aimed at strengthening processes and claims against injustice and social and territorial discrimination, and therefore to promote social justice (Belda-Miquel et al., 2017). The right to the city is not a legal recognition but a social struggle (Kuymulu, 2013) oriented towards the collective self-government of the urban space (Purcell, 2013) so that the production of the city responds to the needs of its inhabitants and not to other commercial interests (Brenner et al., 2012).

This paradigm shift requires profound changes in all sectors (economic, social, political and cultural), from the production of knowledge to policies and practices carried out by actors and institutions at all levels. It is not merely a question to be discussed at an international conference once every 20 years. All institutions need to be forced to take concrete measures to promote greater urban social justice at local and global levels (Pascual, 2016). A struggle that is beginning to gain from the transformation of discourses, that is, from the identification of the causes of the problem and its possible solutions, and from the power relations that determine them (Kipfer et al., 2013). A process that cannot be led by the state, but arises from the creative experimentation of those who suffer the most from exclusion and segregation insofar as their needs become the engine of change in *"motivation, mobilization and Commitment"* (Max-Neef et al., 2010: 34).

The role of experts and professionals will not be to lead the processes of change, but to put themselves at the service of the excluded communities to make visible the structural causes of their exclusion and support them in their efforts to realize their rights (Vidal, 2009).

This vision of the role that professionals and experts must play implies important challenges regarding the training they must receive in the numerous disciplines related to the production of the city: architecture, urban planning, engineering, law, sociology, economics, etc. These disciplines should begin by incorporating the socio-spatial justice and sustainability approaches into their curricula if they really want to respond to the challenges of 21st century cities and not to other interests (Ngau, 2013; Zarate, 2017).

"In our opinion, it is time for the academic community to seriously rethink and redefine its role in society and in sustainable development efforts. This may require changes in how universities conduct operations, teaching, and research.... More than ever, holistic and cross-disciplinary initiatives are needed to link academic into a truly sustainable learning environment and experience." (WEF ISCN-GULF, 2017: 3)

"...is the time to implement a 'very different educational imagination' – one with equity at its core ... Listening and responding to communities who have in the past been 'excluded, silenced, marginalized and ridden over' and fostering meaningful connections with them." (Smyth, 2012: 9-11)

It should also be understood that exclusion and poverty are not only a matter of material dispossession, but above all a political issue, related to the position in the social space and the linkage that is established with the rest of the power structures. In this structure, professionals and experts are not neutral actors, as is often wanted to make them see. If they really want to promote urban social justice, they must put themselves at the service of people and communities private of power to increase their capacities and support their struggles (Freire, 1970, Frediani, 2007, Elizalde, 2007, Cabrera, 2015). They must be willing to give power, and to prioritize the interests of these communities over other possible interests.

As far as urban planning is concerned, this is a crucial question, insofar as planning has been systematically conceived as an instrument of control at the service of established power (Sevilla-Buitrago, 2008, Ngau, 2013), As an instrument it can be transformed or re-created to become a relevant tool to combat socio-spatial inequalities.

"Urbanism must return to life, but this time not to destroy or discipline it, but to open the doors: new tools will be necessary, new methods still to be done" (Sevilla-Buitrago, 2008: 157-174).

"I was more interested in the ways that planning could be used to ensure equitable distribution of resources and services.... I saw planning as a tool for social engagement" (Ngau, 2013:6)

"Facing these challenges undoubtedly requires a personal, ideological and political commitment to the field of urban research and management, with colleagues and with the generations that are forming." (Cabrera, 2015:468)

Keys to forming promoters of socio-spatial justice

The question that arises below is therefore how to move from traditional training on "urban development" to a training centred on the promotion of socio-spatial justice. Or in other words, how to move from learning the design of the "formal" city to learning to promote the co-management of urban space, in order to promote "the right to the city" for all people and to address the challenge of the widening gap of socio-spatial inequalities in cities around the world. It is considered that this learning must be collective, active, integrative and critical.

“In both stages, and incrementally, students develop a critical understanding of the ways that the social and the spatial are entwined in urban space through devising and conducting action-oriented and people-centred acts of design research. Students actively engage with ...local communities, and the material conditions and socio-political complexities of a place.... knowledge are recognised as a collective production... Our educational approach starts by questioning the role of the expert and the way in which discourses of expertise are constituted in particular contexts... The Studio unfolds through a continuous dialogue within workgroups – often through role-plays – whereby design is understood as a non-linear process, influenced by the multiple and often divergent aspirations of different parties” (DPU, 2015:6-7)

“Social issues, inclusiveness and working more closely with community-based organisations were to be at the forefront of our programme.... Our students must be equipped with the relevant skills to address dynamic urban growth and inequality.” (Ngau, 2013:10 -19)

First, it must be assumed that the generation and production of knowledge must be understood as a collective effort between different actors (community organizations, public and private institutions, etc.) (DPU, 2015). A knowledge that must respond to the real needs of the population (Cabrera, 2015) and therefore be rooted in the concerns and challenges of the affected communities, who must be the protagonists of their own process of change (Max-Neef et al. Ngau, 2013, Belda et al., 2016). The professionals, researchers and / or experts are only an actor at the service of this communities.

An active training, that is oriented towards the resolution of real challenges (WEF ISCN-GULF, 2017), located in a specific context (DPU, 2015) in which students are invited to get involved to participate in the actual processes of promotion of greater social, spatial and environmental justice (DPU, 2015). In the specific case of training for the promotion of urban social justice, students should be immersed in real contexts of vulneration of the right to the city in order to be able to know both the needs of the excluded communities and their capacities to prioritize and respond to the challenges they face.

An integrative, trans-disciplinary learning with the capacity to: link theory and practice; understand the complexity of the object of study, that is the diversity of elements and actors involved and the relationship between them; make visible the conflicts of interest and mediate to overcome them in favour of the excluded community in order to rebalance as much as possible the initial imbalance of existing power relations (Álvarez et al., 2015).

A critical learning, as the result of the process of reflection-action. A learning that allows to make visible the structural causes of the exclusion as well as the capacities and collectives proposals co-produced with these communities to overcome them.

These pedagogical dimensions, explored in the previous paragraphs, are considered the starting point for urban education to really contribute to the fight against inequalities, both local and global, in the production of knowledge and of the urban space.

Following we present the results of the case to finally draw conclusions.

From theory to practice: The case of the Observatory of Removals in Brazil.

According to the 2017 Census, Brazil has more than 6 million unoccupied properties, a number higher than the housing deficit, which is 5.4 million units, as a result of the lack of housing policy coupled with the high concentration of property on the part of the dominant class. Culminating in a problem of complex solution that is tangent to particular interests.

A group of studies formed by professors and students from the University of São Paulo (USP), named Labcidade, was born in 2009 to understand the transformation of the urban environment and its process of peripheral expansion, supporting the diffusion of research related to the theme. One of the developments of this group of studies is later transformed into the Observatory of Removals that is consolidated in the year 2012 with the purpose of studying the appropriation processes and the informal city in the metropolitan area of São Paulo.

The main objective of the Removal Observatory is to make removal processes visible in the metropolitan region, giving voice and empowerment to the affected communities, through their participatory actions.

The project achieves its objectives being directed from two fronts, the collaborative mapping and collaborative actions both in the communities. In this way, the project is redefined in the field of action research, broadening its objectives of identifying, mapping and understanding at different scales, people and groups affected by forced removals from their dwelling areas and their causes (relatório final de projetos, observatório de remoções; 2016).

The map is co-produced using a GIS-based platform where everyone can contribute to the database by uploading information about affected communities with help of any device that has access to the internet. The purpose is that the platform can be appropriated by affected families, communities, lawyers and researchers in the area offering them a more accurate and reliable database.

In addition, for a participatory mapping the actions also are dividing between: Facebook site, which has helped communication between communities and researchers, as well as creating various practical activities and the “Pill’s project”, which are short quick videos published on Facebook and Blogs networks that help to visualize the living conditions of those affected.

A second step would be the project “*Observando de Perto*” (Observing closely), which, apart from the analytical exploration of the case for research purposes, the Observatory’s action may also, together with those affected, produce against proposals for expropriations, as well as a greater knowledge of the socio-spatial reality of settlements, instrumentalising this population, in order to strengthen it in the struggle for the right to decent housing and the city (FAU-USP, 2019). The final report of the project was published in Portuguese, helping to disseminate the actions carried out by the Observatory for a greater extent.

The project has grown a lot in recent years with a help of the most varied resource, one of them was The Ford Foundation with a financial support. Besides this, the collaboration and support for the creation and feeding of the web platform has been among them: residents and former residents of areas affected by removals and entities of society involved with the agenda; partnerships with social movements for the housing rights; besides to readings of databases of the public defenders of the city and news published in the press.

Today, the project encompasses approximately 868 cases of threats of expropriations and partial expropriations in São Paulo, Santo André, São Bernardo do Campo, Diadema and Mauá, reaching 287,926 thousand families; esteem almost 1 million people under these conditions, which would be equivalent to 10% of the total population of the municipality of São Paulo.

In any case, we can detect that the actions created have actively contributed to solving the most urgent issues of these communities, since these collectives gain visibility and empowerment, in order to strengthen their networks and stimulate the formation of a common identity.

However, it was possible to establish a general and behavioural view of these evictions by identifying a pattern in the eviction processes in the metropolitan area of São Paulo, as well as to draw a profile of these communities, reasons, actors involved and procedures. Most of them are made up of a population of greater social vulnerability whose conditions of occupation are linked to the deficiency of the State’s public housing

policies. These populations often originate from expropriations; eviction of formal or informal rent, high occupation of clandestine plots in risk areas such as favelas and slums or even housing complexes, prison population and homeless.

The practice of generating a mapping of these communities and of making this information public, besides serving as a denunciation of the precariousness of the public housing system, helps in strengthening the resistance of the affected communities, enabling the articulation between communities that go through a similar process. In this way the mapping opens the fields to other researchers and collaborative actions.

In a country where the lack of public policy and guaranteed access to quality housing benefited the concentration of private property by a dominant political elite makes throughout Brazil's history "illegal" occupations become the main form of access to housing and the right to the city by the most vulnerable population. However, all the actions mentioned demonstrate that collaborative activities show the ability of communities to make effective access to the city, even though in practice their rights are not guaranteed by the State.

Finally, as a great challenge, the replicability of this model is being studied at the moment, being able to extend the platform at national level, the compatibility of the database created with other Brazilian universities will help to highlight the problem on a national scale, and that could be used for the elaboration of a national plan of housing policies.

In conclusion, we must see the action-research initiative as a break from the historical and classicist model where the university should serve society. It is important to affirm that collaborative action is not simply a transfer of knowledge between the university and community, but construction of knowledge together, as a shared process of knowledge. This active sharing between researcher and resident is based on libertarian education, in which to build knowledge together one must recognize oneself as being unfinished as proposed by (Freire, 1970; Angileli, 2007).

In this way, it is intended to make the debate an inclusive, participatory and educational process for both sides, horizontally. When locals, leaders, social movements recognize themselves as producers of knowledge and not only viewers become more critical and aware of the process in which they live (of whom I serve, and what patterns I reproduce) (Angileli, 2007).

The role of the University in the promotion of socio-spatial Justice

In a context of persisting multiple forms of poverty and growing inequalities, it is our duty as educators and professionals to put our knowledge and skills at the service of the excluded communities to fight with them so that their right to the city becomes effective.

"It is the responsibility of the planning profession – including planning educators – to change perceptions... We have realised that we need to approach planning in terms of how it can be of value to people, rather than as an imposition from above... Universities can be part of this process. They can be innovative and responsive; but they cannot push for change in isolation." (Ngau 2013:17)

In this article, it is shown how the Removal Observatory has contributed to produce a collective and integral knowledge with the set of actors involved: Residents, university, social movements, professionals, etc. An active training, oriented towards the resolution of real challenges (WEF ISCN-GULF, 2017), in which students are invited to get immersed in real contexts of vulneration of the right to the city in order to be able to know both the needs of the excluded communities and their capacities to prioritize and respond to the challenges they face. A critical learning, as the result of the process of reflection-action. A learning that allows to make visible the structural causes of the exclusion as well as the capacities and collectives proposals co-produced with these

communities to overcome them. These pedagogical dimensions, are considered the starting point for urban education to really contribute to the fight against inequalities, both local and global, in the production of knowledge and of the urban space.

The experiences presented in this work have contributed to show that housing exclusion is a structural issue and that the way to its solution goes through empowering individuals and their communities to make their rights effective. The case studies show the relevance of the co-production of knowledge between different actors (affected, social movements, academics) and of different forms (formal and experiential), and their potential to make visible the struggles of socially excluded communities as well as their capacities to elaborate collective proposals that allow their right to the city to become effective.

Researching schools vs. researching with schools. An urban research laboratory experience in an Italian high school

Francesco Aliberti¹, Elisa Avellini²

Abstract: We have tried to develop an innovative way to approach educational practice to promote synergies between school teaching, academic research and society. Through a transdisciplinary approach we have tried to prepare high school students to the challenges of researching, thinking and therefore planning about their own territory. This experience was conducted with a group of 23 teenagers from a high school in the periphery of Rome, elaborating an original project of work-based learning inside the school. As tutors of their work, we tried to guide the students divided in five research groups, each one with a specific focus related to the territory where their school is located to the creation of a research project. Students were introduced to different tools with the aim of creating an interdisciplinary methodology, like interviews, focus groups, production of emic maps. Besides the nonetheless interesting results of all the research projects carried on by the five groups, what the participants learned has been a more complex way to reflect and argue upon urban territory, trying to manage change. In our view, this approach to deuterio-learning can be seen as a way to give future citizens the tools to imagine and design the future of cities.

Keywords: educational practices, work-based learning, interdisciplinary methodology, deuterio-learning

Introduction

In this paper we will describe our attempt to develop an innovative way to approach educational practice, not only to give specific notions to students, but also to promote synergies between school teaching, academic research and society.

This work envisaged several objectives. From the point of view of "pure" research, we wanted to increase our knowledge about the relationships of the School with the surrounding territory, trying to observe it not as a place or an institution, but as a subject present within a specific territory, with which it must necessarily confront, with the aim of opening a new strand of research in the field of urban studies and urban planning through the study of this report carried out in an interdisciplinary way. The attempt is therefore to address such a large issue through a "micro" approach, focused on a small case study, thus allowing the beginning of a discussion on the topic. In particular, we wanted to do this through the observation of the relationship that students from secondary school have interwoven with the territory where their institute is situated. This would also be helpful in understanding how the new generations confront the urban space, in what ways they think about it, represent it and act on it.

On the other hand, we wanted to provide the students with tools necessary to learn to think reflexively about themselves, their city and their role as citizens. The goal was to get them to figure out how to imagine the future as a cultural fact (Appadurai, 2013) and how to design it, thus imagining also the future of the territory where they live. These instruments, in particular, are the methods of qualitative research, particularly in the field of urban anthropology, urban studies and architecture.

In fact, we started from the conviction that the future should not be simply considered as what follows the moment in which we live, but as a cultural project whose participation must be extended to as much people as possible. According to Appadurai, the openness to the practice of planning the future goes through the diffusion of the idea of research as human right.

This is why it is important to deparochialize the idea of research and make it more widely available to young people with a wide range of interests and aspirations. Research, in this sense, is not only the production of original ideas and new knowledge (as it is normally defined in academia and other knowledge-based institutions). It is also something simpler and deeper. Research is the capacity to systematically increase the horizons of one's current knowledge, in relation to some task, goal, or aspiration, (ibid.: 282).

The ability to have aspirations is also connected with that of planning, a fundamental ability to distribute in an equal way for the whole world, to allow each individual to put into practice the work of the imagination that processes the future as a cultural fact.

With this work we have also attempted to integrate more two areas of study that in recent years are conversing but still not close enough, such as social anthropology and urban studies. The work has in fact been done as a moment of research-learning, in which the ethnographic data has come to build itself in the interaction with the subjects of the research, which have at the same time learned the basic methods of the research in the city. In fact, we have built as a tool of work an urban research laboratory within which the students would be actually in charge of a piece of research and we would be only their supervisors. The results of their research and what we can deduce, not only tell us something about the relationship that the new generations of citizens have with the territory, often a not-so-good relationship due to great difficulties in planning the future, but also tell us about how much often in Italy the school can become a non-significant place or a non-place at all, except for the personal initiatives of teachers or headmasters particularly interested. The good news that results from our work is that if the researchers decide to confront more strongly within the schools, they can achieve great results by simply letting students know the research methodologies to be applied to their daily lives and to the analysis of the territory in which they live.

Field and methods

Our workshop was held inside the Liceo Orazio, a high school focused on humanities of Montesacro, a neighbourhood in the northeast outskirts of Rome. Before we started our work, we confronted with some of the teachers. These preliminary meetings brought out two main problems concerning the possibility of having students undertake different paths aimed at stimulating their active participation: the distance of the university and the poor quality of the paths of Alternanza Scuola Lavoro -ASL- (school-work alternation, moments of recent introduction in Italian schools, in which student are made acquainted with public or private working environments in the context of training placements).

On the one hand, in fact, in high schools, in particular in such high schools as Liceo Orazio that imagine the student as "of course" destined to continue his studies, since it is already gaining access to an education deemed of excellence, the university is perceived as a distant institution, that does not give the right importance to the work of the high school teachers, as if this was a lesser value, and not interested in being seen in schools, if not

when obliged. This sensation is renewed with the inauguration of the ASL routes. If, in fact, teachers and administrative managers of schools can understand that the paths of ASL within companies are more aimed at practical activities, or otherwise do not expect some great commitment on their part, many are disappointed by the scarce commitment of universities that offer very few projects compared to the actual possibilities and only rarely able to confront the student with a “university mentality”.

All this relates then to a third and much more serious problem identified by the teachers: the lack of moments and spaces in which the children, rather than simply having to assimilate notions, could put to work moments of self-reflection, reflecting about themselves and the context where they live.

So, we decided to create an urban research laboratory that, beyond its objectives of research and teaching, was based on a precise methodology, that of deutero-learning (Bateson, 1972)

Rather than "to teach" the participants of the project how to do research through frontal lectures, we decided first of all to bring out key topics of social research from the reasonings made by the students in their everyday life experiences. This is not an easy task, because the pupils were interested in talking mainly about big topics and they could hardly find themselves in their closest contexts. The methodology used can be defined as a method of research-learning, because the ethnographic data comes to build not so much and not only according to the observations that we could accomplish once inside the school, but mainly originates from the reflections made by the students themselves once they have been engaged in research paths. The attempt, in short, was to identify a communicative strategy to try not to rebuild the “teacher-student” dynamic, as a dynamic that would have obliged them to perform the tasks assigned to us and nothing more, but to set moments of deutero-learning instead. This neologism proposed by Bateson (1972) refers to a type of collateral learning, whereby in the moment of learning something one learns to learn, to build in one way or another the plan of the real and the flow of the events; it is according to Bateson a process of learning not dissimilar to the ways in which we acquire the mental habits that constitute our daily attitudes. In this sense, the proposal of our work was not so much to teach the method of social research, but above all to make the students know and assimilate a self-reflective attitude, which seems to us not dissimilar from what is proposed by Appadurai with the concept of research as human right.

We tried to achieve this result with communicative strategies through which we tried to propose ourselves as intermediate figures, positioning ourselves halfway between students and professors. While remaining their tutors and then invested with a certain authority, as well as the task of expressing a judgement on their work at the end of the project, we still tried to make ourselves accessible, with stratagems that might appear insignificant, but that were instead functional in their presenting themselves as "opposites" compared to the rituals that build the "time" of a school lesson. We therefore asked the students to call us by name and not by surname; we would often tell anecdotes of our lives to let us know and emphasize how we are generationally closer to them than to teachers; rather than position ourselves in front of the kids we preferred to sit with them and spread out in the classroom. Finally, we created a group on WhatsApp in which we can chat together, where to provide service communications but also joke.

All of this clearly involved a certain challenge in managing the work of students who, once understood our "lack of firmness", try to exploit it more than once to get out of their homework or take long breaks. It was a behaviour legitimate to expect, absolutely consistent with their role as students. But the more our figure moved away from that of a teacher and the work they have to do was different from those of the "task", the more we noticed that the willingness to cooperate increased.

In addition to these communicative tricks, we also worked with some classical instruments, replacing or at least masking our explanations with moments of focus group and brainstorming. So we tried to get to the concepts that we are interested in transmitting always passing through the interpretation of the pupils, trying to

understand what according to them meant to do research in a general sense and then what according to them would have been interesting to investigate, helping them to articulate their observations.

Development of the project

Between November of 2017 and April of 2018, for a total of 70 hours, we held the workshop "the job of the researcher: Doing research in the city", which involved a group of 23 teenagers between 15 and 18 years.

After a first introductory meeting in which we introduced ourselves to the students and told them our research work to give an idea of the variety of topics that can be tackled in urban research, we organized different meetings in the form of brainstorming, circle time and focus group to get together with them to define what it means to do research (the most interesting answer was: "To have a purpose"), on what can be the technical and methodological tools in the hands of a researcher and what it means to do research in the city.

To familiarize the children with these issues, we also ask them to make some emic maps (Micciché, 2009) of the neighbourhood where the school is located, also as an exercise to understand the ways in which everyone perceives the space around them differently, then to propose themes that they would have wanted to face during the research, so that we could orient ourselves in the drafting of "calls for research" that we would then have written for them.

If in the drawings there was no relationship between the school as an institute and the territory lived by the pupils, with the latter that sometimes disappears, or with the school itself that often remains relegated to a corner, point of departure or arrival of the paths traced by the students, but never filled with particular connections with the rest of the neighbourhood, the research proposals seemed to aim to explore the possibility of an opening of the school boundary to what is their everyday life out of school spaces.

«Why students do not use the common spaces offered by the school»

«Why are there no beautiful murals in Montesacro? »

«Why are there so many fascist posters in the neighbourhood? »

«Why do some barbers in the neighbourhood don't want to cut girls' hair, even if they have short hair? »

Starting from these cues and from others born during the first meetings, we divided the students into five groups and assigned each of them a "call for project" invented by us, which they were required to participate responding consistently to our requests, as if they were actually getting funds for their research.

1. The first group should have presented us with a proposal for projects on the subject: "The other, the professor. The uses of the school space by the teachers", imagining having to make a real ethnographic survey of teachers of the school. The goal was obviously to put students to the test with the need to reason their relationships against individuals very different from them;
2. A second group would have to answer the call called: "In my days... The generational prejudices on the uses of space "thus dealing with comparing the use of the space of the neighbourhood for leisure purposes between their experience and those of adults who they could interview;
3. The third group was asked instead to respond to the call entitled "To dwell in Montesacro, an approach between history and biography.", thus asking to gather the life stories of the neighbourhood and to tell its story through the experiences of the people that they would interview;

4. The fourth group would instead focus on the production of stereotypes in a work titled "Ways of Being. Distinguishing themselves through the body and through space", which asked students to think about how through the management of their own bodies and the choice to attend certain places people try to adhere to certain styles and tastes;
5. The fifth and last group had to think about the characteristics of space that are not immediately visible or tangible in the call "The invisible space", in which we asked them to reason about those symbolic characteristics that provide certain places determined meanings, stigmas, atmospheres, etc.

Although always through examples taken from their everyday life, in the calls the students were asked to face anything but simple concepts.

So, on returning from winter holidays they brought us their proposals in response to our calls. Each project proposed by them, which we will now see in detail, would have then be developed in the following months. This also meant taking the pupils on the field, where it was necessary, to make them do interviews, photographs, "walks" to notice the spaces of the neighborhood, etc. Back in the classroom we then elaborated all the data obtained in real research, which the students then presented to Sapienza University in front of a public composed of PhD student and professors.

1. The first group proposed a work entitled: "The Other: the Professor. The relationship between student and professor after the new technologies", in which they reflected on how the relationship between teachers and students has changed after the arrival of digital technologies in school spaces. The students conducted several interviews with both their companions and some teachers, coming from the definition of two categories of technologies present in the classrooms: the official ones, those that were introduced on ministerial decision, as the class computers or interactive whiteboards; the unofficial ones, i.e. the various smartphones that students and professors always carry with them and which are sometimes used also for educational purposes but often as recreation;
2. The second group built a research entitled "The use of space in the free time: a generational confrontation", both through various interviews with inhabitants of the neighbourhood, and the drafting of a personal diary drawn up by each member of the group and on which they have reasoned all together. Their work led them to conclude that the ways of using the public space of the neighbourhood in their spare time have only changed relatively over the years, showing how it distorted the idea that current generations would spend less time out of their homes than their parents;
3. The third group interpreted the task of collecting life stories of the neighborhood by focusing in particular on their school, investigating through special "stories of school life" how uses of school spaces in the years has changed, in a search entitled "To dwell in the Orazio. The use of school spaces between yesterday and today ".
4. "Are we just what we show? The stereotypes between prejudice and orientation", is the survey proposed by the fourth group. Methodologically, this group used both semi-structured interviews and questionnaires, based on photos that were shown to the interviewed. In their conclusions, they highlight that, as well as people, even places can undergo stereotypes that change the ways in which everyone can use them. These stereotypes, even if sometimes negative, would serve people in order to be able to orient themselves more easily in the space dividing it into, sometimes too rigid, categories;
5. The fifth group finally focused on the ways in which the area where they are located is contested by various political parties through the use of posters and writings on the walls, which they go to create what the student have called a "written landscape". In the research entitled "metonymy or Synecdoche? The lettering on the walls and the image of the neighbourhood.", the pupils observed how the visual

experience of a place contributes to give to the latter certain meanings, through interviews and photographic reportage.

Besides the nonetheless interesting results of all the research projects carried on by the five groups, what the participants learned has been a more complex way to reflect and argue upon the urban territory, trying to manage change. In our view, this approach to deuterio-learning can be seen as a way to give future citizens the tools to imagine and design the future of cities.

But what we noticed during our work with the students, which was the initial difficulty to get involved in thinking about the neighborhood where they live and go to school, it is present on their daily background. On the one hand, this was totally out of the classical schemes of school education, which instead always led them to imagine the school space as strongly separated from that of the neighborhood, on the other, this asked them to imagine themselves as active citizens, which did not seem to have happened very often.

This has led us notice how little the school is present as an active subject within the territory, but only as an object. In a nutshell, the school does not seem to produce relations with the territory, nor stimulate the children to do so. The relationship of the children with the school itself also seems to have become increasingly less of affection (even when it was hateful) and increasingly "professional". The pupils we worked with in fact managed their relationship with the school with the same pragmatism with which a worker organizes his own holiday plan. It is necessary to manage the hours of ASL, the other laboratorial hours and the possible absences to spend at strategic moments.

But the students are the first to complain: they would like to find within the school the tools suitable to orient themselves among the possibilities of their present. As we have seen, these needs to be able to find in school what is outside is manifested even as we work together with their projects. In the last meeting, in which we asked the students to give us suggestions to improve the project for the next years, the necessity to meet the territory of Montesacro outside the Orazio boundaries was underlined several times.

Conclusion

Through the construction of an urban research laboratory within a high school of the outskirts of Rome, we have created a research project that would allow us not to investigate "the school" but to investigate "with the school", more precisely with its students.

This research-training pathway, activated through the methods of deuterio-learning and in particular by building a context in which students were required to be themselves a group of researchers supervised by us, allowed us to achieve multiple goals.

In fact, we have increased our knowledge in relation to the school's relationships with the surrounding territory, trying to observe it not as a place or institution, but as a *subject* present within a specific territory, with which it must necessarily confront, with the aim of opening a new strand of research in the field of urban studies and urban planning through the study of this report carried out in an interdisciplinary way. In the same way, we discovered something about the students' relationship with their school, coming to notice how often it refuses to let them be in contact with all that part of the world outside the school walls, leaving them without tools to imagine themselves as active citizens. All this, obviously with the necessary exceptions constituted by professors or particularly proactive principals, is not actively supported by the ministerial institutions.

At the same time, however, we have tried to fill these problems at a micro scale, providing the children with useful tools to learn to think about themselves, their city and their role as citizens. By deprovincializing research, we have tried to provide young people with the tools to manage and orient the huge range of interests

that are able to develop into more precise aspirations for the future, but also tried to build bridges between school and University.

Thinking about future developments of this research branch, we hope that researchers and in particular universities as public bodies will be more involved in school environments, trying not to look at them only as places where to collect qualitative or quantitative data but rather as places where knowledge can be produced with the children.

Teaching planning for the transition

Reconfiguring Teaching/Learning/Action/Research: Apparatus for Socio- Spatial Transformation with/in Disadvantaged Rural Regions

Jamie-Scott Baxter¹

¹ *Leibniz Institute for Research on Society and Space, Jamie.Baxter@leibniz-irs.de*

Abstract: The following article presents an adapted theoretical and methodological framework used to rethink and analyse social innovation at work in socio-spatial transformation. The framework is operationalised through a novel teaching/learning/action/research programme that supported local and collaborative spatial planning with/in a disadvantaged rural region in the United Kingdom. A *diffractive* reading of Gabriel Tarde with Karen Barad leads to the dimension of ‘spatial spread’ within the concept of social innovation being reconfigured through the posthuman turn, providing a novel apparatus for collaborative transformation through experiment and situated learning.

Through this apparatus, which draws on advances in critical cultural theory, in particular Barad’s ‘Performative Posthumanism’ the paper reveals how material–discursive practices are agential in the reconfiguration of boundaries and the distribution of agency, calling into question ‘stubborn dualities’ as in this case, the teacher-researcher, activist-professional, local-nonlocal and human-nonhuman.

Keywords: Social Innovation, Situated Learning, Collective Agency, Spatial Planning with More-than-humans

Introduction

There is growing body of evidence supporting the claim that social innovation is well placed to drive social change, meet local needs and address today’s most pressing global challenges (e.g.: Ayob et al. 2017, Defourny et al. 2014, Howaldt et al. 2014). And, how social innovation (SI), is put to work through the social and solidarity economy (SSE) to operationalise territorial transformation (Moulaert et al. 2013) and more recently, addressing local development challenges in disadvantaged rural regions (e.g.: Bock 2012, Christmann 2014, Richter 2016, Noack and Federwisch 2018). However, as the research within this paper shows, local needs do not always align with wider regional, national or global strategies for sustainable development and transformation. While social enterprises, co-operatives, and community based organisations often have strong views about local environments, many non-professional SSE

organisations, especially in disadvantaged rural regions can ‘lack specialised knowledge and training (EC 2013). According to further reports, social innovation and the SSE has the potential to drive social change but is hampered by ‘insufficient knowledge..., limited support of grass roots and social entrepreneurship activities, poor diffusion and little scale-up of good practices’ and further by ‘fragmented capacities and skills.’(BEPA 2010). This lack of specific knowledge, expertise and coordination between spatialities can also inhibit the spread of social practices, which according to some literature (e.g. Howaldt and Schwarz 2010) is constituent to the concept of social innovation. This raises the question: how is connectivity made across territories and, can it be improved to co-generate and transfer knowledge and spatial practices supporting the SSE deliver global, regional and local socially innovative and democratic strategies towards low carbon, resource responsible and fairer societies. In this contribution, I develop the assumption that universities, through their unique positions as part of wider research/practice assemblages are well placed to fill the void in ‘specialised knowledge and training’; improve spatial connectivity; and, through an experimental learning approach cut together with contemporary design-thinking strategies, directly support the social and solidarity economy deliver carefully conceived yet, novel solutions to address global challenges in/between local situations. To aid this objective, the article sets out a theoretical framework to clarify, analyse and rethink the problem of connectivity, co-generation and spatial spread. It attends to the specific research question; how, within such assemblages do specific practices function to co-generate and spatially spread social innovation within the field of sustainable development and socio-spatial transformation.

Based on recent theoretical advances the paper begins with a brief description of social innovation as a transformative force active within the SSE. The following section illustrates the broad spectrum of SI, highlighting how it is operationalised in territorial transformation and more recently, in the development of disadvantaged rural regions with reference to SDG17. This section ends by bringing to light some of the contradictions at work in sustainable development and spatial planning in the U.K., providing context for the following empirical data under analysis. A short discussion addressing collective learning within SI follows, with reference to SDG 11. The paper plots a precise course showing how social innovation cuts across and connects the social and solitary economy, education/research and spatial planning and transformation. I establish a theoretical and methodological framework to rethink and analyse the diffractive force of spatial spread within social innovation drawing on advances in critical cultural theory, in particular Karen Barad’s ‘Performative Posthumanism’ Here we find the thrust of the argument: by attending to how certain boundaries are enacted, we may begin to pursue a more democratic and trans-disciplinary apparatus for transformation. Through this framework, empirical data from a single case study is analysed to reveal how specific practices enact boundaries in/between the fields of spatial planning, civil society and higher education.

Social Innovation and Social and Solidarity Economy

In transformation research innovation and new social relationships between individuals, civil society and states, as well as the economy and science are paramount to supporting transformative change (e.g. UNECE 2012). New forms of social contract and joint responsibility rely on democratic governance, a spirit of participation and an obligation towards future generations and can be enacted through the SSE (WBGU 2011). In parallel to this field, social innovation is described as a process through which social change emerges, where new social relations (e.g.: Ayob et al. 2017) and social practices are intentionally reconfigured (Howaldt et al. 2014) to better satisfy the unmet needs of a society (e.g.: Ville and Pole 2009, Zaph 1989). Such new combinations of practices engendering social change may be regarded as

collaborative and participatory (e.g.: Moulaert 2013, Pestoff and Hulgård 2016), achieving empowerment through democratic governance and co-production (e.g.: Pestoff 2009), and are exchanged through mechanisms of non-linear, social learning (Bock 2012, Howaldt et al. 2015, Moulaert et al. 2013). Novelty is strongly associated with these practices (e.g.: Rammert 2010, Zapf 1989) however, not necessary new universally, but where pre-existing practices spread spatially and become adopted in a new locations (e.g. Christmann 2014). These fields of research clearly overlap through social change, participation and democratic governance, but where transformational research aims towards, as Karl Polanyi (1944) referred a, ‘Great Transformation’, social innovation can provide insight into the microprocesses and mechanisms agential in change. To this end we may draw out three interrelated dimensions of SI to help orientate the study, these are: *social practices*; *spatial spread* and; *social change*.

Where social practices¹ are reconfigured meeting specific, often localised needs through which new social relations emerge. These practices are typically diffused, or spread spatiality and together these dimensions, through a participatory framework, engender democratic social change. It is the dimension of spatial spread to which this article attends and aims to add further depth.

Social Innovation in Territorial Transformation and Rural Regions

Moulaert et al. (2017) make a compelling case for mobilising the concept of SI in territorial development to ‘trigger transformation’. Through an historical perspective, the authors describe SI as a continuum marked on one side by ‘a practical organisational stream’ as a driver of innovation and value creation, often displayed in social businesses. Whereas, the other side is characterised by ‘proponents of a ‘territorial development’ approach, fostering SI as a concept to meet human needs and aspirations, but also for political mobilisation among vulnerable and marginalised communities’ (Moulaert et al. 2017, p.6)². The analysis shows an historic relationship between SI as force in urban neighbourhood renewal and as potential for territorial transformation and reveals a gap in knowledge as to how SI and the SSE is operationalised in rural areas. In Dargan and Shucksmith's 2008 review into social innovation in rural areas and the LEADER programme the authors conclude, it is difficult to promote local development in places with no history of collective action and, how vital both local and external networks are in rural development and innovation. Supporting this claim, other scholars promote an hybrid approach to sustainable local development in rural regions requiring the interdependency of local and external resources, capacities and networks, including rural-urban linkages for success (e.g.:Bock 2016, Ray 2006, Shucksmith et al. 2016) and underpinned by SDG 11A. Furthermore, Howaldt and Schwarz (2010) note, for the success of social innovation ‘the cooperation (quality) of heterogeneous actors and the existence of intermediary arrangements regarding the organization of processes of collective learning, knowledge transfer, the exchange of explicit and implicit knowledge and at regional and/or local level seem critical...’. Knowledge readily available to businesses and academics on say, examples of best practices

¹ Social practices, according to some are specific, often repetitive forms of ‘action’ or ‘praxis’, ‘with intentional or unintentional political implication’ (Ortner 1984). According to Schatzki, practices are ‘a temporally and spatially dispersed nexus of doings and sayings’ (1996), where the individual is only a
² Moulaert points out that in ‘early 2000’s the neighbourhood and community (re)development movement adopted sustainability and food security strategies providing the basis for current social and ecological movements’ (p.18).

is harder to reach for local volunteers or local entrepreneurs pressed for time and money (Mercator, 2012). Here we are reminded of SDG 17, which emphasises the need for multi-stakeholder partnerships as ‘vehicles for mobilizing and sharing knowledge, expertise, technologies and financial resources to support the achievement of the sustainable development goals in all countries’ (UN SDG 17).³ As this literature shows, the force of social innovation in territorial development has the potential to support connectivity not least through ‘intermediary arrangements’ and ‘collective learning processes’. However, where these connections do not already exist barriers to development are evident possessing a significant challenge to sustainable development.

Sustainable Development, Participation and Spatial Planning in the U.K

‘The purpose of planning is to achieve sustainable development’ (DCLG, 2012), reads the first sentence in the ministerial foreword of the National Planning Policy Framework (NPPF), a new tier of local planning policy introduced by the British government in 2012 to promote ‘a shift in power away from central government towards local people’ (DCLG, 2011). This is followed by, ‘Sustainable means ensuring that better lives for ourselves don’t mean worse lives for future generations’ (DCLG, 2012 p.i). And, ‘Development means growth.’ (ibid p.i). Through the NPPF the government intended to introduce and redirect the planning system towards a ‘presumption in favour of sustainable development’, where, ‘development that is sustainable should go ahead, without delay’ (Conservative Party 2010). The NPPF cites Resolution 42/187 of the United Nations General Assembly which, following the Brundtland Report defined sustainable development as ‘meeting the needs of the present without compromising the ability of future generations to meet their own needs’ (WCED 1987). Up until the publication of the NPPF, the U.K. had signed up to 5 guiding principles of sustainable development set out in a 2005 strategy, Sustainable Development: Securing the Future.⁴ However, despite much criticism (not least from the parliamentary select committee appointed to review the reform)⁵ the NPPF refused a comprehensive definition, referring broadly to the three pillars of sustainable development (economic, social, environmental) alighted to but missing the additional detail of the UN Rio+20 summit. The vagaries around what constituted sustainable development continued to haunt the planning reforms and provide uncertainty at local levels. How these rather abrupt and fundamental changes had intended to be carried out and joined-up between administrative levels, remained uncertain.⁶ Neither the resources nor skills for this new type of participatory governance were available within all local authorities, nor within the local,

³ A sentiment echoed in The Lisbon Declaration – Social Innovation as a Path to a Sustainable, Resilient and Inclusive Europe, released by the Social Innovation Community, which states: ‘Civil society, non-state actors and local communities are empowered to define and address challenges that matter to them, such as climate change; And, research and innovation gives greater recognition to the contribution of civil society and the wider public; And, mainstream innovators (like technologists, firms and research organisations) take up a key role in driving direct societal benefit’(SIC 2018) .

⁴ These are: 1. living within the planet’s environmental limits; 2. ensuring a strong, healthy and just society; 3. achieving a sustainable economy; 4. promoting good governance; 5 using sound science responsibly. (SDC 2005)

⁵ Consensus provided by expert evidence from Friends of the Earth, Campaign to Protect Rural England, Town and Country Planning Association and officials from DCLG through the committee was that the definition of sustainable development within the Localism Act and proposed NPPF was insufficient.

⁶ BY 2020 councils will have experienced a 60% decrease in funding since 2010, with almost half receiving no funding from central government. (Source: Local Government Association)

voluntary SSE who was expected to deliver local sustainable development (where sustainability was ill defined from national policy level down). Compounding the problem further, the required local capacities are not evenly distributed across U.K. communities, with more deprived neighbourhoods having less resources and skill required to undertake complex planning operations than those in affluent areas, a problem especially affecting disadvantaged rural regions.

Social Innovation in Teaching, Learning and Research

As pointed out in the social innovation literature and SDG17 cross-sector collaboration, experimentation and room for social and creative learning provide preconditions for social innovation to occur. Some scholars ⁷ turn to social learning theories to account for the transactionary procedure within the diffusion of novel practices between human agents, however the following case study shows, a closely connected form of experimental and creative learning developed by Lave and Wenger (1990) may provide further scope. Whereas, social learning as theorised by Bandura (1971) relies on the replication of behaviours between individuals through observation, imitation and modeling (Bandura 1971). Situated learning occurs in a social context and drawing on practice theory provides closer attention to ‘learning by doing’ addressing *real* problems in *real* situations. Situated learning is more pedagogical in character, where social learning leans towards an examination of how societies stabilise and change overtime. Through the case study, I suggest situated learning offers a more performative and experimental notion of learning and exchange where the emphasis lies on developing novel practices through the reconfiguration of existing ones, rather than solely on the intentional motivations of human actors. Both theories do however share the notion of a feedback between the practices learnt within a context and the effects of those practices back upon the context. Such forms of experimental learning not only serve to provide education and skills in sustainable development aligned with SDG 4.7, but moreover, individuals participate and enact transformation by identifying challenges and developing new skills and practices required to meet them.

Theoretical Framework: From Diffusion to Diffraction

The mechanisms at work within spatial spread of social innovation remain somewhat underdeveloped in recent literature often relying on an implicit notion of diffusion of knowledge taken from broader innovation literature.⁸ Here, innovations, for example technical innovations are rendered complete prior to knowledge of them being diffused through networks of human actors. Such an anthropocentric view of diffusion where information of innovations is passed between determinate subjects in a linear mode is described by Everett Rogers in his seminal *Diffusion of Innovation* (1995) where, an individual or unit of

⁷ See for example: Bock 2012; Howaldt 2010; and Moulaert 2017

⁸ Howaldt et al. 2015 have provided a thorough discussion on the recourse to Tarde’s work in contemporary Social Innovation research and practice theory to which this work is indebted. The authors elaborate on spatial spread and refer to the work of Rogers. However, they stop short of introducing theoretical advances from the ontological or posthuman turn to account for the immanent and performative aspect of practice. Furthermore the discussion does not attend in detail to Tarde’s intrinsic growth but does emphasise the significance of the imitative spread of practices as an overlooked dimension of social innovation.

adoption communicates new ideas to others in the sequence.⁹ However, since this milestone publication, scholars across disciplines have begun to rethink the world beyond the human. Nonhuman agents within a network or, assemblage are ascribed equal agency as their human counterparts.¹⁰ This attendance to the agency of the world or, the ‘liveliness’ of matter (Bennet 2010) beyond that bestowed upon it by human consciousness has a political and ethical dimension taking it beyond postmodern critical theorising (Žižek 2018).¹¹ As Karen Barad theorises, agency, rather than being an attribute of the human, is instead *performed* in the *intra-action* occurring within *material-discursive* practices. It is through these practices, or *apparatuses* that bodies are constituted and the world is iteratively (re)produced or, *reconfigured* (2007). Through this turn, the spatial spread of social innovation as a real force with real consequences must be thought beyond a representative diffusion of knowledge (about innovations) between determinate human actors. Moreover, the distribution of agency within the production of social innovation must be reconsidered attending to the diffractive propagation of specific (material-discursive) practices (or, apparatus) that serve of co-generate and propel social innovation.¹²

To help rethink the diffusion of social innovation through the posthuman turn, it is to Gabriel Tarde’s work we may look. In his *Social Laws: An Outline of Sociology* (1898) Tarde describes how inventions travel along ‘imitative rays’ propelled by forces of *repetition*; hindered in their journey by counter-forces of *opposition* (like a competing idea or innovation), and; *adaptation* where many infinitesimal ideas or inventions undergo a ‘harmonising synthesis’ through a passage of ‘gradual enlargement’. It is the imitative dimension of his work that has dominated Tarde’s legacy and passed on through diffusion research. However, his law of adaptation may provide a more complex and complete picture of the dynamics of spatial spread in social innovation and the affects therein. Tarde distinguishes between two ‘very much inseparable’ (Tarde 1893) but distinct forms of spread which he figures as growth, or enlargement. That of extrinsic growth, ‘a growth in extension by imitative diffusion’, (1893, 115), here we can think of Rogers’ famous S-Curve which traces the phased adoption of innovations over time. And the second, intrinsic growth which is, ‘growth in comprehension by a series of logical combinations’(115). It is intrinsic growth that is foundational to his law of adaptation and of interest to this particular study. Tarde writes, intrinsic growth is ‘the tendency of a given invention or social adaptation to become larger and more complex by adapting itself to some other invention or adaptation, and thus create a new adaptation, which, through other encounters and logical combination of the same sort, leads to a high synthesis, and so on’ (115).^{13 14}

⁹‘The essence of the diffusion process is the information exchange by which one individual communicates a new idea to one or several others’ (Rogers 1995, p.18)

¹⁰ See for example: Anderson and Macfarlane 2011, Braidotti 2013, DeLanda 2006, Deleuze and Guattari 1987, Law 1986, etc.

¹¹ As Donna Haraway presents a, ‘...version of the world as active subject, not as resource to be mapped and appropriated in bourgeois, Marxist, or masculinist projects. Acknowledging the agency of the world in knowledge makes room for some unsettling possibilities, including a sense of the world’s independent sense of humor. Such a sense of humor is not comfortable for humanists and others committed to the world as resource’ (Haraway 1988).

¹² In a forthcoming publication I elaborate this notion, drawing further on Barad’s concept of *Diffraction*, Rogers’ concept of *Re-invention*, Uno Yoshiyusa’s *Intercultural Refraction* and Deleuze and Guattari’s *Assemblage* with Tarde’s *Intrinsic Growth* towards a more complete picture of how social innovation ‘spreads’ with/in a posthuman and immanent world.

¹³ Tarde illustrates this adaptive intrinsic growth through the example of the invention of the wheel in combination with the domestication of the horse, both of which he claims spread independently though imitation prior to coalescing harmoniously in the notion of the cart. The new proposition formed through

From Interaction to Intra-action

Differing from assemblage theory as advanced for example by Manuel DeLanda where, distinct and determinate elements connect in relations of exteriority (DeLanda 2006), Karen Barad's performative posthumanism is founded on a philosophy of immanence (De Freitas 2017), a 'one-world ontology' (St Pierre 2018) where things are already intra-connected but temporarily separated through the formation and reconfiguration of specific boundaries. In Barad's work boundaries are produced through the intra-action within material-discursive practice that perform categories, such as *nature* and *culture*. This performativity leads to 'agential cuts' through which specific exclusions are made. In Barad's ontology there are no determinate individual entities, instead in a sense all things are already hybrid and incomplete, in a continual process of coming into being. Permeating Barad's work the concept of *diffraction* is deployed in varying ways but always with a sense of waves propagating, intersecting and adapting in the co-production of new phenomena. The concept is illustrated with the diffraction pattern of light waves intra-acting with a razor blade. Under magnification spots of light are seen in areas that should be dark and object boundaries become indistinct as light waves intra-act. Here we are reminded not only of Tarde's imitative rays, but moreover of his description of a social adaptation becoming larger and more complex by adapting itself to adaptations. Like Tarde's intrinsic growth, Barad's ontology is one of interiority, or more precisely 'exteriority within' (Barad 2007, 93) where all relations are intra-active, occurring within a continually changing and expanding assemblage performed through specific (material-discursive) practices, or apparatus. Through this diffractive reading of Barad with Tarde, spatial spread is no longer the discreet citation of an innovation spanning territory; rather, it is a diffractive enfolding and enlarging of intrinsic combinations of adaptations of adaptations.

Reconfiguring Teaching/Learning/Action/Research

Before continuing, I would like to introduce a drawing (Figure 1) that maps the interactions (relations of exteriority) within a typical spatial planning project. The illustration depicts the three separate fields I have discussed so far spatial planning, civil society and teaching-learning-research and the practices constitutive of each. As can be seen, the practices are distinct and separate with clear boundaries delineating them serving to reinforce the divisions between fields. As practices move closer to each other a space at the centre opens up for collaboration between fields. Other interactions are of course apparent between practices across fields but always in a relation of exteriority. Through the conceptual framework advanced above, the following case study analyses how such boundaries between fields are reworked.

the adaption of its constitute parts is no mere summation, as Tarde points out. That is, the product of this particular set of alliances is greater than the sum of its parts. It has the character of multiplicity or as Delueze and Guattari (1983) present near a century later, that of assemblage

¹⁴ In *Anti-Oedipus: Capitalism and Schizophrenia* (1983) Felix Guattari with Giles Deleuze adapt Tarde's example to first illustrate their notion of *assemblage*, where the domestication of the horse, in combination with innovation in riding technology and subsequently techniques combine to become the warrior-horse-bow, a war machine greater than the sum of its parts and possible only, according to Guattari (2009) under the condition of the great steppe. Here we see the adaptation of innovations and their affect not only on practices and constituents of the assemblage, but also affected by and with affect upon the space in which they are reconfigured. And, as Guattari points out, within this assemblage man is more-than-human, becoming a constituent part of the machine (Guattari 2002)

The analysis addresses the specific (material-discursive) practices coalescing around one particular workshop within a three-year project consisting of many other interrelated events and practices.

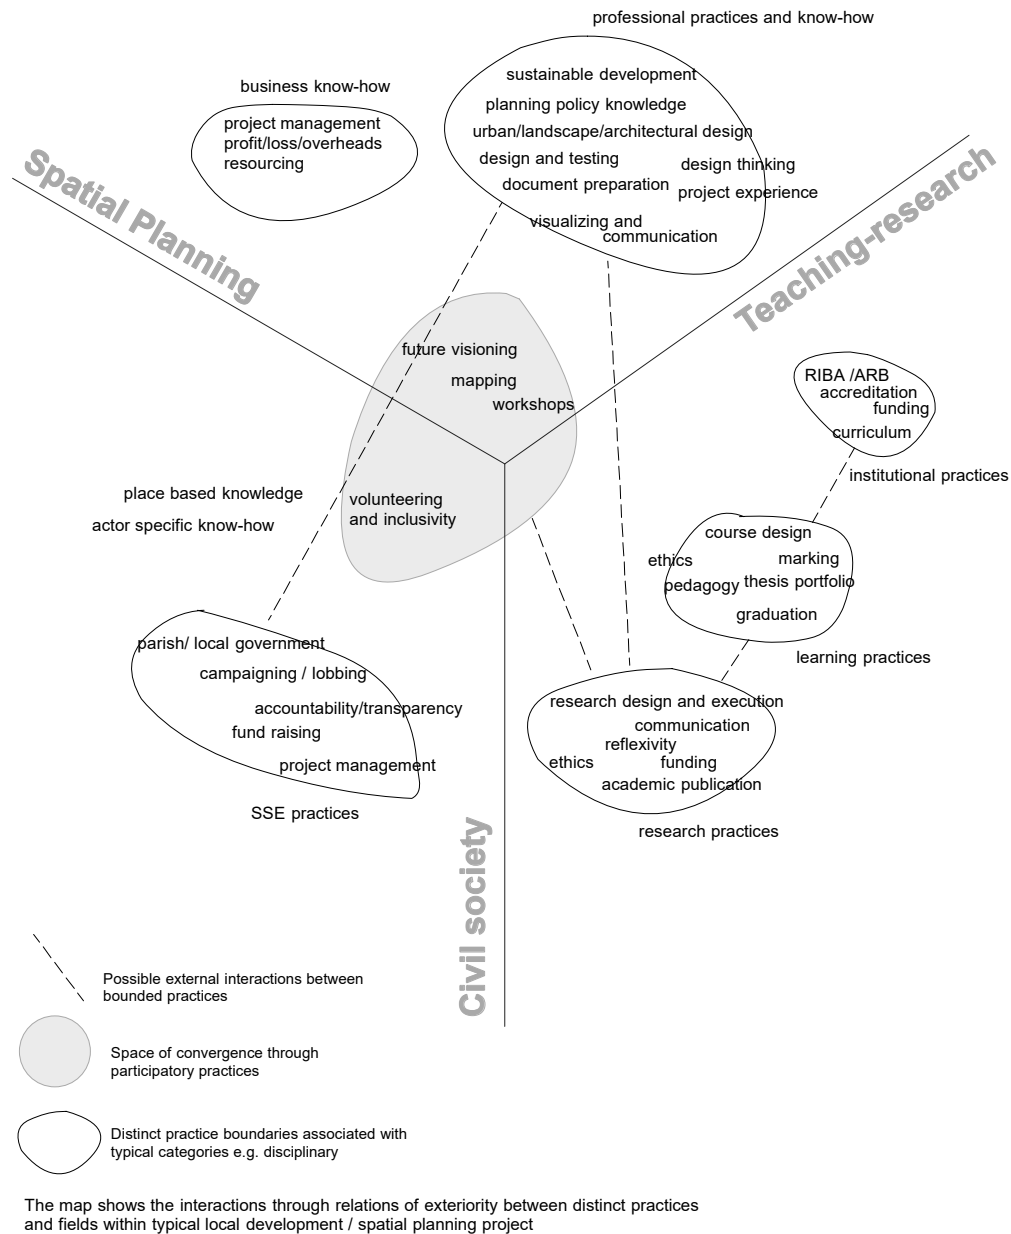

Figure 1. Interaction Map

Within the context of the new planning policy framework sketched out above, a group of academics and practitioners from the spatial planning field and construction industry designed a novel action-research and learning programme at a London university. The project acted as an intermediary, where together students, staff and other professionals supported disadvantaged communities in rural South-east England co-produce and deliver a new spatial development plan. Through a call for participants, three villages

were selected from a shortlisted to prototype the program. The region was selected as it displayed typical challenges associated with disadvantaged rural regions across the U.K. and Europe such as, perceived threats due to broader demographic changes and urbanisation processes and long-term lack of investment, access to resources were restricted and a lack of local capacities and finances were evident. Academic staff in the group had previously experimented with teaching programmes in which MA architecture students were given access to *real* situations and *real* challenges within communities. However, thus far the solutions conceived by students and teaching staff and had had little impact beyond the academic context. The new prototype programme combined situated learning practices, spatial planning practices and advanced co-design methods in participation. By linking to wider professional network students were provided with access to extensive skills and resources beyond the university context. The program facilitated a reciprocal relationship with the three villages developing novel practices for teaching and learning whilst simultaneously co-generating solutions jointly identified local development challenges in the context of planning reforms. Here we are reminded of the dimensions of social innovation set out above where novel (material-discursive) practices are spatially spread (now a process of diffractive enlargement), to reconfigure new social relations through participative (intra-active) procedures.

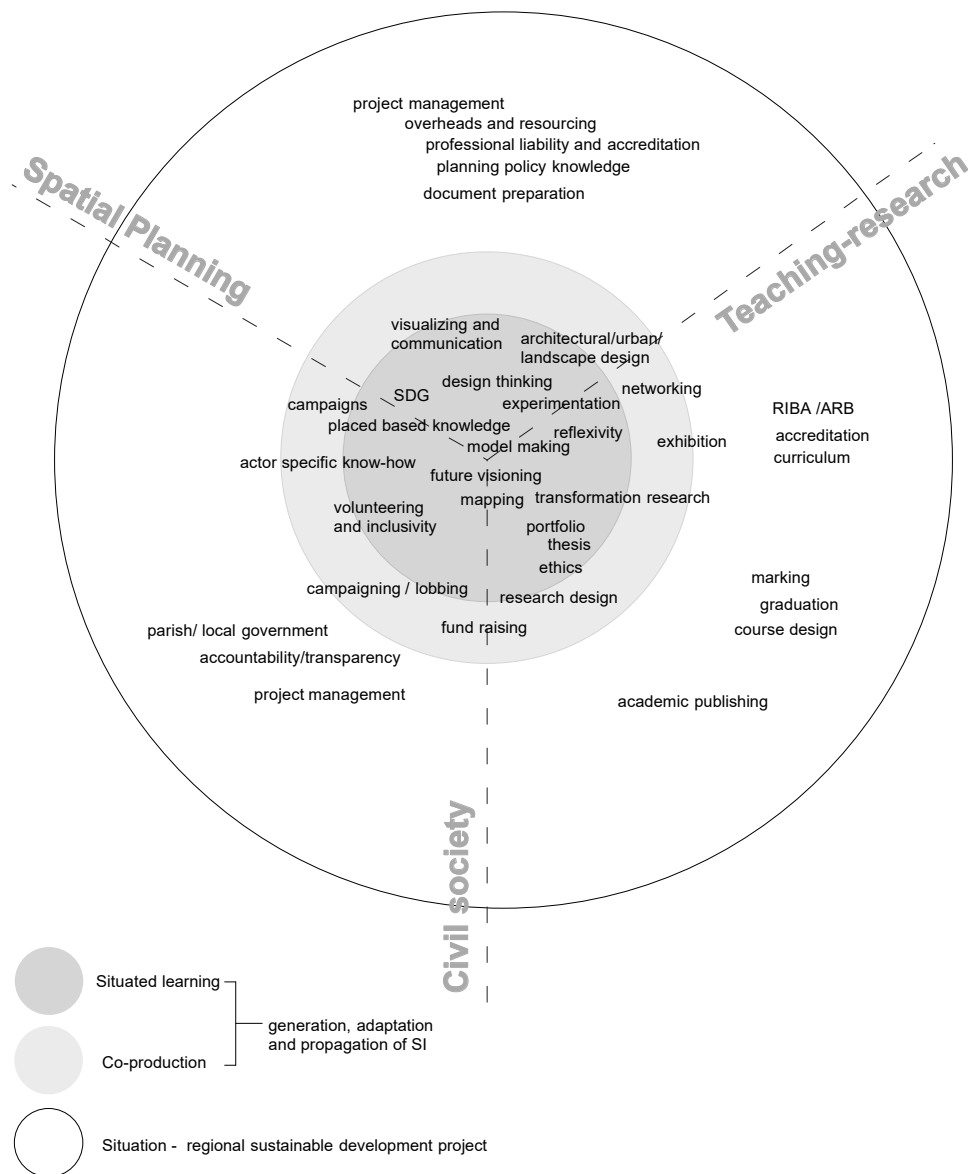

Research Methods and Ethical Matters¹⁵

Innovation biographies, initially developed by Rammert (2010), trace the history of an innovation, often technological but more recently social (e.g. Butzin and Widmaier 2012) in a biographical mode from conception, through development and spread. Textual biographies are usually reconstructed through qualitative interviews and document analysis and can be triangulated with actor-network or constellation diagrams. Traditional innovation biographies however have a bias towards a linear chain of cause and effect in the very biographical nature of the method. In attempt to overcome this restriction and to shift focus from human actors towards a more complex distribution of agency within (material-discursive) practices, I introduce a more spatial and experimental¹⁶ mode of research through map making. Adapting the innovation biography, I locate, map and analyse the specific practices within the case study attending to how boundaries were performed, as shown in Fig II. An analytical mapping of the specific practices and their constituent parts reveals the formation and diffusion of specific boundaries, including those between disciplinary fields. Mapping data are gathered and triangulated through a participative action-research with notes, interviews and extensive document analysis gathered through the duration of the programme. This form of analysis and theoretical framework brings into light assumptions that may otherwise remain obscure and provoke fundamental philosophically orientated questions.¹⁷

¹⁵ The author of this paper was a researcher/practitioner in the action-research programme. Action orientated research has received much criticism for the positionality of the researcher within the object of investigation, however Barad's performative posthuman framework rejects the notion of objective separation maintained in the pursuit of research, but rather attends to the agential role of the agencies of research in the materialisation of phenomena. (Cf. Barad 2007).

¹⁶ Here I refer to Elizabeth St Pierre and Elizabeth de Fretias invitation to a more experimental approach social science research, one that supports a project of mapping rather than tracing. See for example St Pierre's New Empiricism (St Pierre 2018)

¹⁷ This mapping method is currently being developed within the research programme RurAction (see acknowledgements above) and the Hybrid Mapping Working Group hosted at TU Berlin and in collaboration SFB 1265: Re-Figuration von Räumen.

The map shows the intra-action in/between specific (material-discursive) practices serving to erode boundaries between disciplinary fields.

Figure 2 Intra-action Map

Analysis: Modeling and Boundary Making Practices

Perhaps less commonly known to non-spatial planning professionals, scale models are often used during a design phase of a project to experiment and test proposed interventions. Here, a three-dimensional description of say a neighbourhood is made where houses, roads, public spaces etc. are constructed out of

wood, paper, card or other material at a scale appropriate to judge how a new physical intervention relates to the wider urban context. In contrast to presentational models, which are often static representations of a singular vision, this practice of modeling is open ended, exploratory and experimental.¹⁸ There is a dynamic relationship between the proposed intervention and the wider context within the model, of course the human hand is a part of this apparatus, but where agency is not a sole attribute of the designer. There is room for unintentional and unexpected relations to emerge with/in the model. What seems like a very material practice relies as much on a discursive dimension not least through the verbal communication of ideas with colleagues. This communication engages in discourse outside of the localised situation often relating to particular schools-of-thought in which the designers position themselves which in turn co-produce 'the object of which they speak' (Foucault 1971).

The case study intended to share such generative practices with/in communities to facilitate a democratic, co-operative and co-productive 'learning' environment. To this end, a co-design workshop was conceived where the generative and experimental modeling practices outlined above were taken out of the expert's studio and brought to the village for all to participate in. The co-design workshop centered around an elaborate three-dimensional scale model of the existing village built by students and staff from card, wood and paper. Crucially, no proposed interventions were produced prior to the workshop. As ideas and proposals were co-generate in the three hour workshop by all those present they were quickly prototyped from card and foam and placed into the model for consideration. This facilitated an immediate and transparent critique between experts, students, staff, community etc.. As an interviewee pointed out, trust grew through the fact there was no a preconceived solution presented during the event, rather the 'experts' and 'students' alongside 'locals' critiqued the proposals as they materialised through the workshop. The co-design practices were adapted from other city based participative projects to suit the specific needs locally. The adaption and co-generation of these practices and their enactment served, in part, to diffuse the rigid boundary often reproduced between expert and laypersons. Furthermore, through the spread and adaption of the practice (from city to rural region) a new, albeit temporary connection was made across the apparent rural/city divide. A difference in relations was observable at the end of the event where a new camaraderie was evident which was less perceptible at the beginning, where antagonisms between local/expert-other were observable. Furthermore, as Barad points out, discursive practices are not confined to the 'lab' and intra-act with concepts and discourses extending beyond the physical space in which the apparatus is situated (2007). This has multiple connotations and consequences, one of which is that the boundaries of apparatus are not fixed and through discursive practices extend spatially. This is evident in the apparatus of the co-design workshop, where the practices extended beyond the room in which the event took place and indeed the particular temporality of the event. The workshop took place in summer 2016 which coincided with the lead up to the EU referendum in the UK. At the time, some of the

¹⁸ In spatial planning practices, scale models are often used to display a determinate proposal within an existing built context. Here, the scale model is a rather static tool, a representation with more or less singular purpose, to communicate one group's vision (usually the designers) of a location to another group (either the users, clients or planning authorities etc.) Within this set of common practices a clear boundary is reinforced between the model makers and those asked to accept the intervention presented within it. Such boundaries usually follow a division between project roles and often along disciplinary lines.

national media aligned with the leave campaign¹⁹ aimed to (re)produce a division between ‘rural working class’ and ‘metropolitan’ or, ‘liberal elite’²⁰ to bolster an argument for leaving the EU.²¹ During the workshop these discourses could not be ignored and were performed locally through placard and posters displayed in gardens and windows reiterating affiliations with the leave campaign. The results of the referendum show the village voted leave. Furthermore, comments on the co-design workshop posted on an internet forum reveal some distrust towards the intentions of the workshop. We begin to see the tension here between the gradual diffusion of place-inscribed boundaries through certain practices (e.g. trust and camaraderie gained through developing and participating in shared practices) and the violent agential cuts serving to exclude and (re)produce divisions (e.g. local/nonlocal, rural/urban). This brings to the fore the power of such apparatus beyond the intentionality to carry out participative spatial planning.

A further concrete example of boundary making practices performed with/in the apparatus of the workshop can be seen in the significant shift in position with regard to development. The workshop begun with a strong and vocal anti-development sentiment within the group, but through the course of the event this position moved as an opening up towards additional housing at the edge of the village was experienced. It was evident that the model, associated practice of prototyping and critique was agential in this shift. This was manifested in the gradual erosion of the settlement boundary that circumscribes the village. A symbolic red line performed through local planning policy with very material consequences, not only to more development but also ingrained in attitudes towards nature and the built environment more generally. The material and discursive boundary of the village separates green space from built space, which, in this oft performed duality we can more broadly say represents the familiar nature/culture divide. In U.K. planning law and in the imagination of parts of the population, (particularly those concerned with the protection of rural environments) this boundary is more-or-less sacrosanct with a long and contested history affecting urbanization processes and the morphology of the U.K. However, in the case, the immovable ‘red line’ shifted through the course of the workshop to speculate on a significant extension to the village crossing the existing settlement boundary. We can say through the apparatus of the workshop, the space of the village began to be reconfigured in the imagination of those present and simultaneously in the physical space of the model (through prototyping). This new space was propagated through the repetitive practice of council meetings and minutes over the course of the following year and, would it not have been for a competing, oppositional force a year later (here we are reminded of Tarde’s repetition, opposition and adaptation) this new space would may well have actualized in planning policy and eventually resulted in reconfiguring the 1:1 space of the village. The symbolic dimensions should not be overlooked here. Through the apparatus a mental boundary had been reworked expressed in the acceptance of new development but with more profound consequences. The rigid cut between nature and culture, enshrined in planning law and routinely performed had been called into question. In doing so, not only were the perspectives of the human subjects reworked, but also the positionality of the human subject in relation to the object of nature was addressed. At first glance, from a sustainable development perspective, building on green field land may not be considered best practice, but this critical

¹⁹ E.g. ‘If you believe in Britain, vote Leave. Lies, greedy elites and a divided, dying Europe’ MailOnline 26th June 2016

²⁰ E.g. ‘May Savages Liberal Elite’. Daily Mail. 5th October 2016

²¹ Within this discourse, the ‘privileged elites’ who represent and are represented by the metropolis (London, the seat of political power) were out of touch with the needs and desires of the white working class, embodied by disadvantaged ‘rural’ areas, left behind by the prosperous ‘city elite’.

repositioning serves another purpose that is, to shift the ingrained ideas which perform a separation between human and nature through which nature is easily accepted as an inert resource, available for human consumption.

Lines of Flight

I have shown how reforms to national planning policy served to create confusion and misalign local, national and international goals for sustainable development. Specifically, where local desires towards development did not align with national economic agendas under the contested umbrella of sustainable development. Where local knowledge, capacities and skills were unable to cope with the pressures brought about through planning reforms an innovative programme developed through a university was initiated as an intermediary to support and contribute towards the development of the SSE and co-produce local spatial planning policy. I have shown how the programme exhibits traits associated with concept of social innovation and how it aimed to facilitate and stimulate social innovation locally whilst spreading practices spatially connecting regions. The concept of social innovation cuts across usual disciplinary fields connecting spatial planning, civil society and experiential teaching/learning practices in an effort towards sustainable transformation. The approach exemplified in the case study and reworked through the theoretical frame of this paper clearly has scope to be reproduced at other universities and in association with the UN's HESI. Furthermore, the paper provides an adapted theoretical framework through which social innovation and spatial spread have been rethought opening up a new dynamic space for further inquiry, and where ethical and philosophical matters may be considered. Finally, the notion of participation (core to the concept of social innovation) was been reworked from relations of exteriority, exemplified by interactions between determinate actors or disciplines, to relations of interiority characterised by intra-action, where agency is distributed and performed through (material-discursive) practices. As illustrated in Figure 3, practices, fields and categories usually thought to be distinct and separate are enfolded into a diffractive and expanding apparatus at work in socio-spatial transformation.

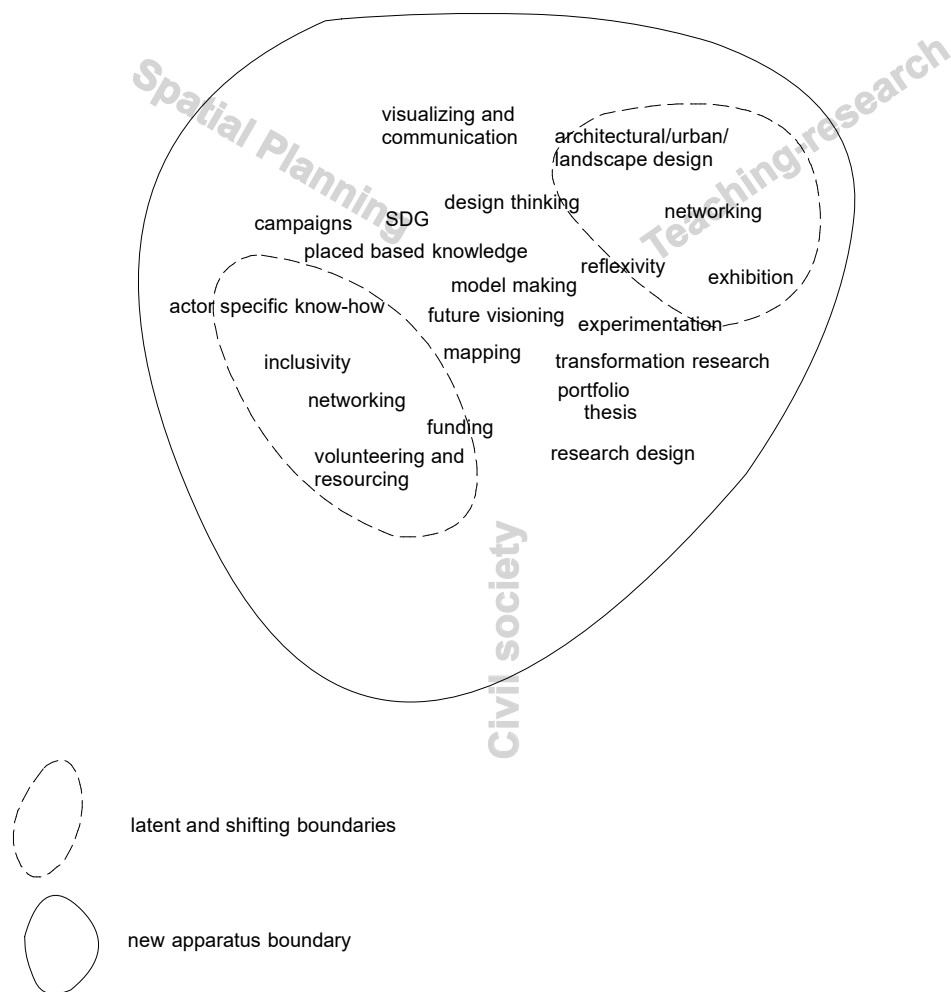

Figure 3. An abstracted model of novel apparatus in social innovation and transformation. The diagram depicts how practices are connected in a relationship of interiority where previous boundaries between fields are reconfigured.

Acknowledgements

The research presented in this paper as been carried out under the project RurAction: Social entrepreneurship and social innovation in structurally weak rural regions. This project has received funding from the European Union's Horizon 2020 Marie Skłodowska-Curie Actions (MSCA) Innovative Training Network (ITN) programme, grant agreement No 721999

Integrated Development Planning - Polish Practice And Didactic Challenges

Paweł Churski¹

*¹Institute of Socio-Economic Geography and Spatial Management of Adam Mickiewicz University in
Poznań*

Abstract: The analysis aims to present the bases for integrated development planning and its use in the practice of spatial management, paying attention to the challenges related to the higher education in this field. The research procedure is made up of three stages. The first stage involves the synthetic systematization of basic theoretical premises of integrated development planning, taking into account the differences in definitions and suggested approaches in the Polish literature. The second stage presents the selected examples of challenges regarding the operational use of this conception in planning practice in Poland. The third stage shows the project of a unique field of study, Integrated Development Planning, that started in the 2018/2019 academic year in the Institute of Socio-Economic Geography and Spatial Management of Adam Mickiewicz University in Poznań under the Knowledge-Education-Development Operational Program's project entitled Integrated Development Planning – the forge of a new cadre of professionals for the sector creating the development policy.

Keywords: integrated development planning, theoretical assumptions, practical implementation, Poland.

Introduction

Current global and local conditions contribute to an increasing deficit in free space, leading to social and functional conflicts, larger investments and their influence on surroundings, and also a growing uncertainty regarding the stability of undertaken measures and their long-term effects. Under these conditions, a dichotomic system of public planning, that continues in many countries, also in Poland, is far from optimal. This leads to the conclusion, considering the systemic nature of the objects of planning, that planning processes (socio-economic and spatial) must be integrated. Integrated development planning ought to grow into a basic approach to programming and implementation of measures related to development intervention aiming at the improvement in spatial development. It should enhance the efficiency in the limitation of differences in living conditions and in running business activity to the socially acceptable level.

The analysis aims to present the bases for integrated development planning and its use in the practice of spatial management, paying attention to the challenges related to the higher education in this field. The research procedure is made up of three stages. The first stage involves the synthetic systematization of basic theoretical premises of integrated development planning, taking into account the differences in definitions and suggested approaches in the Polish literature. The second stage presents the selected examples of challenges regarding the operational use of this conception in planning practice in Poland. The third stage shows the project of a unique field of study, Integrated Development Planning, that started in the 2018/2019 academic year in the Institute of Socio-Economic Geography and Spatial Management of Adam Mickiewicz University in Poznań under the Knowledge-Education-Development

Operational Program's project entitled *Integrated Development Planning – the forge of a new cadre of professionals for the sector creating the development policy* (POWR.03.01.00-00-N055/16-00).

Integrated development planning – Polish understanding

Integrated development planning is one of the approaches to programming and implementation of measures related to development intervention aiming at efficient limitation of differences in the living standards to the socially acceptable level (Faludi, 2006; Molle, 2007). Planning constitutes a stage, which according to Henri Fayola's systematization, apart from organizing, managing and controlling, creates the basis for the management process, related in the case of integrated development planning to places understood as countries, regions, communes – territories (Alajlani et al., 2010; Audretsch et al., 2006). The management which, due to contemporary socio-economic changes connected with transformation and postmodernization enhanced by integration and globalization (Naisbitt, 1982; Churski et al., 2017), migrates from the private sector in which it developed to the public sector where it finds new applications. Its importance increases in the conditions of growing risk resulting from uncertainty about the direction and sustainability of development processes (Ziobrowski, 2015). The primary objective of integrated development planning is an attempt to join within its scope economic planning and spatial planning that leads to the integration of its subjects, levels and documents. It also involves the integration of planning dimensions towards a complementary consideration of the economic, social, spatial, ecological and institutional-political aspects, which places them on the foundation of sustainable development assumptions (Turner, Pearce, 1992). As Markowski and Drzazga (2015, p. 16) notice, breaking the present dichotomic system of public planning in which “...*there is a contradiction in proceeding and implementation between the sphere of economic planning and spatial planning...*” is on the one hand a pressing need, and on the other, a specific challenge. It leads, considering the systemic nature of subjects (i.e. countries, regions, communes – territories), to the conclusion that it is necessary to integrate the aspects of planning (socio-economic, spatial, ecological, institutional-political), which would ensure the inclusion of the whole, determinants, objectives and specificity of the course of development processes, which, as Parysek (2016c, p. 42-44) claims, should become “...*the foundation of the reconstruction of the planning system in Poland...*”.

The growing interest in integrated development planning and attempts at its operational use in the practice of the development policy result from the tendency of the last decades towards decentralization of public competences and strengthening a local level strongly limited after the 2008 financial crisis (Mazur, 2017). It is also the effect of the implementation of its new paradigm to European regional policy, which is based on the OECD conception (How regions..., 2009; Regions Matter..., 2009) applied in the Fabrizio Barca Report (2009) and called place based policy. Its use is of particular importance in the context of the popularization of the endogenous development conception applied in the explanation of states, changes and consequences of spatial differences, very well embedded in the theoretical bases of economic geography and economics (Churski, Kołsut, 2017). Integrated development planning and endogenization of development processes permeate each other in the practice of the contemporary development policy. They are of particular importance for the local level, natural for an optimal recognition of resources and relations creating local territorial capital and on this ground planning and implementing efficient development activities at this territorial scale.

According to Markowski and Drzazga (2016, p. 17-18), “...*integrated planning is a holistic process of setting goals and building paths to achieve objectives set in this process, taking into account the most*

important interdependencies (relations) between the most significant elements of a controlled system. Integrated planning understood in this way, related to socio-economic development, in its creative process of setting and achieving goals has to take into account quantitative and qualitative market and non-market relations occurring between the elements of subsystems: social, economic and a broadly understood living environment...". Integrated planning should lead to the elimination of contradictions resulting from the dichotomy of the public planning system by creating conditions for the implementation of an integrated planning process. They hold that (2016, p. 17) "...the essence of integrated planning is not to achieve integrated development (as sometimes indicated), but to integrate a planning and decision-making process which, if properly applied, should lead to a high level of integration of the social, economic and spatial subsystems and thus ensure development objectives, including sustainable development...". Parysek (2014, p. 17) draws attention to the dilemma over the approach to integrated planning which can relate to the planning process or/and its result, i.e. plan: "...in the case of creating an integrated plan one could say about the integration of a structure (structural aspect), whereas in the case of the integration of planning, the integration of the process (planning) is involved...". He is clearly in favour of integrating the process, that is planning, with limited, according to this Author, possibilities of implementing integrated plans for practical applications (Parysek, 2014; 2016a). Kudłacz (2015), in turn, highlights the lack of systematically thought-out synchronization of socio-economic and spatial planning, emphasizing at the same time that the integration of mechanisms for the regulation of spatial and socio-economic development processes should concern three elements: policy, planning and implementation of arrangements. On the other hand, Woźniak (2015) distinguishes three aspects of the integration of development planning:

- integration of planning levels,
- integration of subjects of planning,
- integration of planning documents.

The first one concerns the integration between the existing levels of planning – European, national, regional and local. A functional hierarchy should be in force here, based directly on the principle of subsidiarity. The second level refers to the basis of integration of the subjects of planning which should be a joint perception of different public policies and sectoral and thematic tasks. Finally, the third one pays attention to the need for the integration of planning documents, the process which should not be limited only to the unification of documents, but ought to aim at ensuring content-related coherence between them. Interesting proposals concerning the implementation of the indicated aspects of development planning integration are presented in the Polish literature by Parysek (2014, 2016a), Markowski (2014), Noworól (2014) and Kudłacz (2015). In addition to the diagnosis of the present deep dichotomy of the planning system in Poland, they draw attention to different variants of implementing the idea of integrated development planning. These proposals are based on both the evolutionary approach involving a gradual integration of present solutions intended for the replacement of present approaches and tools with new ones and the radical approach based on the need for rapid changes and implementation of new solutions.

Taking into account the present arrangements and importance of integrated development planning, three basic aspects should be considered (Churski, Motek 2016):

- the pursuit of sustainable development,

- regularities in spatial differences of socio-economic development and spatial development,
- the evolution of public planning.

Integrated development planning should be considered in relation to the progressive departure of modern society from the concept of socio-economic development based on simple quantitative growth in favour of qualitative changes. In this context, the theory of sustainable development¹, popularized globally by, e.g. Brundtland Report (Report of the World..., 1987), defining this process as such an exploitation of resources, directions of investments and technological progress as well as institutional changes that remain in harmony and improve both the present and future potential for the satisfaction of human needs and aspirations (Blowers, 1993). Integrated development planning should be analyzed in the context of regularities in development processes which are diversified in space depending on individual conditions, factors and processes which result from their differences as well as the lack of efficient intervention measures intended for the convergence of the development level using the compensatory model dominating at present in the development policy (Churski, 2014a, 2014b). Benefits resulting from the implementation of the idea of integrated development planning related to balancing development processes and convergence should constitute a sufficient condition for adapting the planning system to the implementation of such measures. As Markowski (2014, p. 1) states „... the need for integrated development planning by public authorities is so obvious that postulating its introduction seems a sheer truism...”. As emphasized by Markowski and Drzazga (2016), the essence of integrated planning boils down to the integration of planning and decision-making processes. The integration of the planning process, as Parysek (2014, 2016a) points out, is therefore a prerequisite for the full inclusion and coordination of socio-economic, spatial and environmental processes in pursuit of sustainable development of the EU territories, which is one of the main objectives of the Community. “...This is so because economic and social development are generators of changes in spatial development, whereas the natural environment determines the framework of solutions...” (Parysek, 2016a, p. 44).

This leads to the conclusion that the idea of sustainable development can and should be treated as the superior, indicating the goal and concretizing the assumptions of integrated development planning at every spatial level. Its significance at the local scale is particularly important. This is so because it allows a complementary approach both at the stages of programming and the implementation of development measures making full use of endogenous resources of territorial capital, its links with the surroundings as well as opportunities and limitations of strategic and spatial dimensions, present and future development processes concerning local communities inhabiting, developing and managing a given area.

Integrated development planning – Polish practice

Despite the indicated objective benefits related to integrated and holistic thinking about planning, the implementation of integrated development planning in the Polish practice of the development policy encounters a number of barriers resulting from both the functioning of hierarchical and sectoral organizational structures deeply embedded in public administration and also a very consolidated bureaucratic system of values and interests. A major obstacle, as Parysek (2014, p.18) writes, is also “...*the lack of clarity as to the meaning of the integrated plan and integrated planning...*”, accompanied

¹ See, e.g. Rogall (2011)

by objectively existing differences in the functioning of the socio-economic system (high dynamics and unpredictability) and the spatial system (high inertia) and also no institutionalized planning structures of integrated planning. What is also important is the specific devaluation of the term “integrated” in Poland, which has recently been extensively used and also overused in the context of measures implemented only in a seemingly coordinated way taking into account a multi-faceted nature of development processes. So far the attempts undertaken after the end of the 1990s to combine strategic planning with spatial planning have not brought the expected results². In part, it is certainly a consequence of too much political dependence of strategic planning, typical of young democracies and emerging political systems. On the other hand, it should be remembered that the system of spatial planning functioning in Poland rests on imperfect legal bases which enable the occurrence of many irregularities and even pathologies in the practice of spatial development (Parysek, 2015, 2016b).

The dichotomy of the Polish planning system is well-established in law and practice (Table 1). Currently, the legal basis for strategic planning in Poland is specified in the Act of December 6, 2008 on the principles of the development policy (Journal of Laws 2014, item 1649 as amended). They regulate the functioning of obligatory development strategies at the national and regional level as well as program documents and operational programs, the scope of which, however, is limited to the economic and social spheres without strictly covering the spatial one. Their preparation at the local level is optional, but considering the fact that having the strategy is in many cases an *ex-ante* condition for access to public aid, especially financed from European funds, their occurrence at this level is almost universal. It is worth noting at this point that, as usual, the quantity does not translate into quality and many of the prepared and adopted development strategies are only formal documents, not real ones. The sphere of spatial planning is regulated by the provisions of the flawed and conducive to spatial chaos Act of March 27, 2003 on planning and spatial development (Journal of Laws 2003, No 80, item 717 as amended). In accordance with its assumptions, what is prepared at the national level is the national spatial development concept operating alongside long- and medium-term strategies for socio-economic development. At the regional level, shaping and following a spatial policy is based on the spatial development plan for a voivodeship which is again a “parallel” document to the development strategy as well as program and operational documents serving its implementation. Yet, at the local level, communes prepare the studies of spatial development determinants and directions as well as local spatial development plans (LSDP), the latter being legal documents. Unfortunately, in this system an investor can (in the absence of an LSDP) submit a request for issuing a decision on development conditions and land development, which leads to a spatial chaos resulting in numerous very negative socio-economic consequences (Kowalewski, Markowski, Śleszyński (eds), 2018).

Table 1

Dualism of the planning system in Poland

Aspects	STRATEGIC PLANNING SUBSYSTEM	SPATIAL PLANNING SUBSYSTEM

² At this point one should not forget about the valuable experience of the Polish planning system of the 1960s concerning the preparation of regional plans which had the character of integrated plans.

COORDINATION	Ministry of Investment and Development	Ministry of Infrastructure /Ministry of Investment and Development

Source: own study.

Under these circumstances attempts to integrate the excessively politicized strategic planning system with the spatial planning one based on a faulty legal basis cannot bring the expected results. “...A separately functioning system of the public planning of economic development leads naturally to a contradiction in proceeding and implementation between the spheres of economic and spatial planning...” (Markowski, Drzazga, 2016 p. 16). However, not without significance is the fact of self-government activities in this area, which despite obstacles, undertake joint measures regarding territorial planning integration, especially in the metropolitan areas of the largest Polish cities (Kaczmarek, 2015a, 2015b, 2015c).

The present state is indicative of the need to carry out a specific revolution and change the development planning model in Poland using the wide capabilities of information and communication technologies. This is confirmed by both the recommendations of opinion-making circles, including the Committee for Spatial Economy and Regional Planning, Polish Academy of Sciences and the Society of Polish City Planners (Assumptions and directional principles..., 2014) and also the postulates of practitioners of the development policy. This idea is also supported in the circles of the government administration, above all in the Ministry of Infrastructure and Development (Strategically for development..., 2011), and presently in the Ministry of Investment and Development (Strategy for..., 2017; Management System..., 2017). Additionally, legislative changes are planned in the near future – an amendment to the Act on the principles of the development policy. The ongoing work in the Ministry of Investment and Development concerning the amendment to the Act of December 6, 2008 on the principles of the development policy (Journal of Laws 2014, item 1649 as amended) aims to introduce a mandatory

integrated development plan at all the territorial levels of programming and implementation of the development policy in Poland. Unfortunately, the parallel works taking place in the Ministry of Infrastructure on the Town-Planning-Construction Code which was to supplant the Act of March 27, 2003 on planning and spatial development (Journal of Laws 2003, No 80, item 717 as amended) and all “special acts”, and which was supposed to introduce an integrated development plan to planning practice were abandoned. In these circumstances, one should expect that in the second half of 2019 the changes in the Polish development planning system will come into effect, which will become the first step towards its integration. They will be certainly imperfect due to the existing competence dualism (two ministries) and the abandonment of works on the amendment to the Act on spatial planning.

Integrated Development Planning – the forge of a new cadre of professionals for the sector creating the development policy – a case study of didactics project³

Seeing the need for changes in the Polish planning system and responding to the future challenges of preparing human resources for functioning in new conditions of integrated development planning, the Institute of Socio-Economic Geography and Spatial Management of Adam Mickiewicz University in Poznań prepared a program for a new unique course of study *Integrated Development Planning*. The main objective of the undertaken measures was the preparation, implementation and evaluation of the program of engineer-degree studies with a general academic orientation in a full-time and part-time mode. It also included building the cooperation network of scientific institutions and those of the socio-economic environment guaranteeing a full implementation of the assumed education effects in terms of knowledge, skills and competences. As a result of a competition (Competition no 1/NPK/POWER/3.1/2016 for New Education Programs), this project was selected for implementation with the support of European funds at the disposal of the National Centre for Research and Development as part of Priority Axis III HIGHER EDUCATION FOR THE ECONOMY AND DEVELOPMENT, Measure 3.1 COMPETENCES IN HIGHER EDUCATION of the Operational Program Knowledge-Education-Development. The preparation of the program and the implementation of the course were carried out with a full use of scientific and didactic potential of the Institute and wide external partnership including scientific and didactic units as well as economic entities, administration and non-governmental institutions. The project implementation was planned for the period 2017-2002 and its structure embraces two basic tasks. The first one was related to the preparation of the education program, the construction of a mobile information and communication infrastructure for the needs of education as well as preparation and printing of textbooks. The second task involves the current implementation of the first cycle of the education process, treated as a pilot project assuming self-improvement based on introducing corrections resulting from the on-going evaluation. As a result of the adopted measures, a seven-semester program of various parameters was prepared (Table 2).

Detailed objectives of the didactic project include:

- providing knowledge, skills and competences to students concerning the importance of integrated development planning for the optimization of contemporary socio-economic development processes intended to minimize development differences, create conditions for sustainable development and implement a new planning system in Poland.
- strengthening the links with practice in the area of didactics related to integrated development planning, especially in the field of developing practical skills and in the context of popularizing good practices related to the application of this approach in public administration, e.g. by conducting sessions and internships in institutions which are interested parties in the development process and its planning in the strategic and spatial dimension.
- preparing and enriching the didactic materials concerning the importance of integrated development planning in the country's planning system.

- internationalization of studies in the field of integrated development planning (students' foreign internships), resulting in popularization of good practices and their implementation in Polish public institutions responsible for the development policy and principles of integrated planning.
- promotion of project results contributing to the popularization of the idea of integrated development planning as an approach ensuring optimization of intervention measures towards improving the efficiency of development processes.

The education process was based on the modular organization of studies. This means that the whole program is composed of courses which are grouped in modules while maintaining the principles of combining academic knowledge, practical skills and social competences. The adopted principles lead to the use of various methods and education techniques in each module, emphasizing the significance of practical activities, team work and a problem approach. Each module provides for courses in the following forms (at least one in the module structure): lecture, classes/workshop/laboratory, e-learning, one's own work (done individually and in a team in a problem approach), practice – e.g. a meeting with a practitioner, a visit to an enterprise/institution, a case study – field classes, carrying out a project as part of a commission from the economic circles – with at least 50% share of active classes. In each course of this didactic process, both academic teachers and professionals active in the spheres related to the skills and competences trained are engaged.

The process of obtaining the diploma in *Integrated Development Planning* is based on two principal elements. The first one involves semester projects prepared in the selected modules which, collected by students, create their portfolio at the end of the studies, which illustrates the knowledge, skills and competences acquired during the education process. The second element concerns a diploma thesis which is done in a project approach with a wide use of documents collected in the portfolio which is one of the primary data sources for a graduate. The thesis must meet the conditions of an integrated approach to development planning. Thus, it should be based on the integration of the strategic planning and spatial planning spheres and/or integrate three basic dimensions of development processes: economic, social and territorial. The adopted way of obtaining the diploma requires creating special care for the student. It will include the presentation of the principles of the diploma process (an Introductory module at year I), the possibility of taking individual tutorial sessions oriented to the identification of subject and spatial interests of a student and consultations with future thesis supervisors, support of students' counsellor throughout the entire academic year, guidance of a thesis supervisor and subject-related help during a diploma seminar.

The education program was prepared in the process of cooperation with the strategic Partners, i.e. the Ministry of Development – Department of the Development Strategy and the Marshal Office of Wielkopolskie Voivodeship – Department of the Regional Policy. This process involved the following six stages: (1) research into education results in terms of knowledge, skills and competences expected by the socio-economic environment (e.g. employers, self-governments, government administration), (2) establishment of the Program Council as a form of institutionalization of cooperation with the socio-economic environment and parties interested in the education process, (3) preparation of the initial version of the education results concerning knowledge, skills and competences and the initial structure of the modular education program (modules, courses, forms of classes, education methods, number of

hours, ECTS points) which should guarantee the implementation of the assumed education outcomes, (4) verification of the initial version of results and the education program, preparation of the final version of the learning effects and the modular education program and also syllabuses in accordance with the principles determined by the law, (5) construction of a mobile information and communication infrastructure, and preparation of textbooks and scripts necessary for the education process initiating the Polish textbook output and enriching the small scientific achievement regarding the importance of integrated development planning in the planning system in Poland, and (6) implementation of the education program and assumed learning effects in full-time and part-time studies.

A significant distinguishing feature of the prepared course *Integrated Development Planning* is the adopted program, very broad and interdisciplinary in terms of content, which assumes achievements in theoretical knowledge, practical skills and social competences in the field of socio-economic geography and spatial management, economics as well as legal, social, mathematical and Earth sciences (see Table 3).

⁷ The Marshal Office of Wielkopolskie Voivodeship

The assumed interdisciplinarity of the course *Integrated Development Planning* enables graduates an activity in the areas of, e.g. integrated planning of socio-economic, spatial and financial development, creation of the development policy of self-government units, making use of statistical and econometric models, application of new IC technologies, including GIS tools, carrying out individual or team projects. Knowledge, skills and social competences acquired by graduates during the studies allow them to participate in project teams dealing with socio-economic and spatial development planning. They can also work in public administration at the local and government level and take part in the management process in these kinds of units as well. They are substantially prepared to develop applications for co-financing projects from public funds, including EU means. They can also undertake consulting activity related to socio-economic development.

The target group of studies in the field of *Integrated Development Planning* embraces primarily people interested in taking up employment in public administration and presently employed in this sphere of the national economy. As follows from the Report on the need for educating public administration personnel in the area of development management (2010) prepared by the Institute of Socio-Economic Geography and Spatial Management on the request of the Ministry of Regional Development, there is a pressing need to improve the quality of public administration in Poland, especially regarding the competences of the personnel in terms of conducting a development policy taking into account contemporary global trends, including the use of integrated development planning for enhancing endogenous potentials of individual areas.

Summing-up

The above-mentioned facts and regularities lead to the conclusion that integrated development planning is necessary to ensure the effectiveness of intervention measures aimed at sustainable development resulting in improved convergence, being also a basis for the creation of a new, more effective organization of the planning system in Poland.

The presented education project in the field of *Integrated Development Planning* is a response to the need to expand education in spatial management resulting from contemporary changes occurring in society, the economy, public administration and higher education. This program and a new field of study, according to the presented assumptions, should measurably contribute to the creation of conditions for the improvement to the functioning of public administration in Poland in the area of the development policy which should be recognized as crucial for the effectiveness of the country's intervention financed from public means. Thus, the undertaken measures are directly involved in supporting public administration by the higher education sector in pursuit of improving the efficiency of the country, which is one of the key priorities indicated in strategic documents both at the national and EU level. The adopted model of the broad participation of interested parties, including socio-economic circles, in creating and implementing a new field of study and the use of didactic innovations prepared and already tested in practical application by the Institute of Socio-Economic Geography and Spatial Management of AMU, both in terms of the organization and implementation of the didactic process, guarantees obtaining unique and qualitatively distinctive effects of education.

Acknowledgements

The author would like to thank all the Employees of the Institute of Socio-Economic Geography and Spatial Management whose involvement led to the preparation and implementation of the mentioned

project of launching a new field of study *Integrated Development Planning*. Special thanks go to Wojciech Dyba, Monika Herodowicz, Emilia Jaroszevska, Paweł Motek, Robert Perdał, Paulina Perkowska, Krzysztof Stachowiak and Sylwia Staszewska performing functions and implementing tasks as part of the project team.

Teaching urban planning through international cooperation project with African cities in very fast transition times

Daniela De Leo¹, Monica Coralli²

¹ *Rome, Sapienza University*

² *IPP-Institute Polytechnique Panafricain, Dakar*

Abstract: The "African question" is increasingly an "urban question", particularly considering the transition phase and the transformation speed that African cities have been experiencing over the last few years. An important question therefore emerges regarding the quality of the training of urban planners, both in European schools – attended more and more by African students – and in the field of international co-operation between European and African universities, also supported by some recent EU Calls. In this context, this paper is an opportunity to discuss the limits and possibilities of teaching urban planning in a phase of rapid changes and, therefore, to define common strategies to reinvigorate the quality of our teaching and practices of future urban planners, inside and outside the European Schools of Planning while obviously being careful not to succumb to the always concealed neo-colonial drifts that would be even more negative for everyone today.

1. The environmental and educational context

The environmental crises and pollution rates are growing in tandem with the increase in population and very fast urban development of the major African cities. These processes are very swift and supported by international enterprises (mostly by the Chinese) that are exporting a dissipative model of development without considering mistakes and sometimes disasters we have already had in our own countries. For example, following the construction of the first Senegalese highway tracing the Dakar-Thies Mbour axis and the Blaise Diagne international airport in the village of Ndiass (between Mbour and the capital Dakar), the urbanization rate and economic growth of Mbour underwent significant increases by pushing the populations to continuously migrate towards this center. The spread of informal settlements and the difficulty of managing infrastructures created considerable inconvenience to the territory and to the population. A number of neighborhoods appeared in areas subject to flooding, while the rapid urban speculation has not encouraged any planning activities. In this way, the massive population density and its consolidation allowed for no kind of sustainable urban planning. In addition, to the absence of greenery, environmental ill-health is exacerbated by the widespread presence of outdated means of transport, which become the leading cause of air pollution (considerably exceeding the thresholds allowed by law, especially in constantly congested areas).

All these conditions appear accentuated by the weakness of education in urban planning, strictly connected to the sharp reduction in the urban planning curricula within Architecture and Engineering degrees, in the wider context of the closure/failure of a number of important Schools.

In particular, in Senegal, the Faculty of Architecture and Urbanism in Dakar (UAE-Ecole d'Architecture et d'Urbanisme) was founded in 1972 by the then President Léopold Sédar Senghor, who dreamed of excellence in all the arts for Senegal and wanted it to be recognized in Africa and throughout the world. He wanted to be able to form individuals capable of transmitting the values of Negro-African civilization. To translate this vision, based on UNESCO guidelines, the Senegalese State created the UAE within the public university UCAD, with the aim of annually training a hundred professionals able to address the issue of habitat and respond adequately to the needs that arose, dealing with the conception, construction, and management of housing supply.

These architects and town planners were to acquire the skills to intervene in all important decision-making bodies, in order to define an urban context in tune with modernist ideology and canons, adapted to the demographic growth of a

new capital in full expansion. At the time, the SICAP-Société Immobilière du Cap-Vert already been in existence for two decades, and the OHLM-Office des Habitations à loyer modéré had ten years of experience. Senghor had a particular interest in these projects and followed them closely during his presidency. The habitat had to translate spatially – and induce – a new way of life that would be the result of the articulation between various cultures and styles, essentially French (or more generally Western) and African. Complementarity, dialogue, and exchange were the key words of a line of research and approach that simultaneously had to participate in the construction of a new Senegalese and African identity, and in the construction of the "Civilization of the Universal".

Dakar was the place where possible 'compromises' between conservation and recovery of cultural heritage and development were experienced, in a reasoned mix of "Sorbonne et Négritude" (Senghor, 1961). "The Ecole de Dakar", as it was more commonly called, offered a space for dialogue on how to create architecture and think about the city and urban expansion, or even about how to enhance the vernacular and traditional architecture that was systematically defined through at least three important collaborations: UNESCO, BREDA, and IFU-Institut Français d'Urbanisme.

Parallel to the Senegalese initiatives, EAMAU, the Faculty of Architecture and Urbanism, was opened in Lomé (Togo) in 1975. This was the result of an essentially African initiative with the aim of preparing, through highly selective training, an elite capable of taking on the technical-administrative challenges brought about by the Independence of the new French-speaking states of Africa.

Furthermore, several member countries of the OCAM decided to open regional schools (of administration, veterinary, agricultural, etc.) and the creation of the EAMAU was the response to this decision: today it embraces 14 French-speaking and Spanish-speaking countries of sub-Saharan Africa. Its main objective was and still is to produce expert local architects, urban planners, and technicians specialized in urban management who would then occupy key positions in this field. By combining different disciplinary approaches, the aim was to relaunch research into urban planning across the continent and enrich knowledge of the construction of urban spaces, taking into account the cultural, economic, social, and spatial realities specific to the African world (cf. Coralli, Aholou, 2010).

The closure of the UAE in 1991 due to economic problems – students regularly omitted to pay university fees – left a significant gap with respect to the weight that the city had had and still has within the countries of West Africa as the former capital of the organization of the French-speaking states of the West (AOF). Thus for some twenty years only the Ecole de Lomé (EAMAU) remained active, before other schools were established in the different capitals of the West African countries.

In this framework, an interesting aspect is the fact that the French imprint on the teaching of architecture has had a long-term effect on the separation between architecture, urban planning, and territorial planning/management, leading to the progressive weakening of the competent figures who deal with the city and its territory, the consequences of which are still being paid, today more than ever. This separation is now challenged only by the geographers who, however, have less interest and fewer skills for sustainable urban design and transformative addresses, focused as they primarily are on the descriptive/interpretative dimension. Although this latter is undoubtedly necessary, it is obviously not sufficient when there are stronger and more defined market- and economy-driven directions for urban transformation and hasty development.

Visions and competencies seem lost, while the worst effects of mistaken development choices are showing their environmental and social costs all around the world. The increase in inequalities and the lack of awareness about environmental issues require more appropriate knowledge and tools to extend also to the management of waste, the control of landfills, and the significant problem of soil and air pollution.

Nonetheless, in the last 20 years west African cities have never produced design plans with a duration of more than 15 years, while detailed plans are included with priority action programs of 5-7 or 10 years. Nowadays the focus is only on the (economic opportunities of) "the building dimension" and therefore limited to the single lot linked purely with the logic of real estate speculation. This means that construction design is totally uncoupled from the context, both in terms

of understanding the relevant issues and with regard to the objectives of transformation and the effects of improvement of the context itself.

A sustainable development perspective must, however, be imagined within a broader horizon even if, at present, only the Plan Senegal Emergent (PSE) 2014-2018 follows the Documents de Stratégie de Réduction de la Pauvreté (DSRP), and the Stratégie Nationale de Développement Economique et Social (SNDES) provides some initial guidelines for managing environmental issues. However, these tools appear insufficient and sharply at odds with the technical apparatuses and local population awareness with a very low level of information and attention as regards these issues.

2. Our “capacity building” project

According to this larger picture, we believe that Universities (schools of Architecture and Planning) have to play a stronger role in the near future in promoting a different culture of urban and regional development through a thorough and widespread involvement of the population.

But considering the weakness of the Universities and through a small international cooperation project funded by the Sapienza University, we started to define strategies to strengthen the scope of urban planning within the Architecture section of the IPP-Institute Polytechnique Panafricain in Dakar. With the IPP as a partner university, we are targeting actions for developing training capacities suited to the needs of local institutions, the city government, and the citizens.

First of all, this international cooperation project funded by the Sapienza has allowed greater awareness of the difficult conditions of western African cities’ urban development with regard to the priorities, in particular, of Sdg’s 11 goals. And since this collaboration is obviously insufficient to conduct experiments on the field which might bring about concrete urban transformation in terms of sustainable development, we have already submitted proposals for further EU Funds to create real opportunities for exchanging the different experiences of the various Italian and African cities in terms of urban and territorial planning for sustainable development in order to act cohesively in the urban environment.

Our international cooperation project, however, aims to carry out extensive-capacity building action to lay the foundations for a competent and active institutional subject in urban research and specialized training, connected to local and national networks. The expected results of the project concern:

- strengthening research and training capacities through exchange practices;
- consolidation of training structures (possibly with the reopening of the urban planning department) through a closer relationship with the demand from local institutions and third sector organizations;
- creation of a solid cooperation network interacting between training institutions, local, and third sector associations;
- creation of a research laboratory with école doctorale and a second level Master’s course.

Moreover, the collaboration among different Departments of public and private Universities will help them to absorb the deficit in research and professional training in complex urban phenomena and the management of territorial transformation in terms of sustainable development. Thus, by simultaneously structuring actions aimed at research and training in the field of urban studies we aim to analyze plans, policies, programs and their results also in relation to the demand for innovation of the social actors and professional bodies involved.

2.1. The hidden challenge (or the trap) of the professional orders’ role

While working we understood that the targeted strengthening of the planning disciplines has to include an on-going debate among professional orders as to the training contents for the recognition of an adequate role of professions. This means that university education depends, in some way, on the professional orders that decree their quality and role, with obvious implications for the fortunes (and survival...) of the different schools.

Not surprisingly, in Ivory Coast the two founders of the new school of architecture (2016) are members of the Steering Committee of the national professional orders by showing the level of proximity between schools and professional

profiles, and revealing some overlap that perhaps does not allow the training programs to be defined within a broader and more adequate scope.

As a result, technical aspects prevailed over every pedagogical dimension, forcing schools towards professional-only training. In some cases, given that a number of academics teach in their private professional offices, it also merged the work of Atelier and teaching.

Then, as in the worst Italian tradition, the school becomes a place for the direct co-optation of professionals rather than a University that prepares for life, research, and a profession.

In this context, our international co-operation project should help to:

- enter into the debate since the technique and practices have been painstakingly reconnected to research (De Leo, Forester, 2018, Coralli forthcoming);
- support the increasingly evident and sometimes hasty route towards an African States autonomy desiring to rethink and rewrite its own history by being a different interlocutor with respect to the traditional dependence on the French scene;
- share important knowledge with respect to the foundation of Italian urbanism within the faculties of architecture but also in the most recent history of planning courses both inside and outside the faculties of architecture;
- develop the spirit of shared work among different institutions that is different from the support coming from NGOs.

In our sense co-operation has therefore become a tool for:

a) **giving legitimacy** to small universities motivated within a system that cannot be said to ease the survival of quality university education that navigates between the blackmail of the financiers/investors and that of the single evaluators directed towards professionalization. What we are trying to create is a recognized network of professional orders and faculties of urban planning and architecture to check and define possible guidelines for a more adequate training of students and future professionals.

b) **facilitating interaction** with the many stakeholders who today define guidelines and minimum standards for the evaluation of structures in relation to training programs on the basis of a collaboration that introduces competence into the field and reinstates the link between architecture and urban planning. We ourselves are trying to contribute to the debate by putting together as many interlocutors as possible, some of whom are particularly relevant in also being either evaluators or financiers¹. The aim is to stimulate a different debate and introduce new directions by trying to obtain a reframing of last year's statements on the fear of the multiplication of sometimes inadequate private schools, as a response to which they threatened that the diplomas would not be recognized for enrollment in the order and therefore for the exercising of the profession. Then return to the evidence that there would be few architects to carry out the many activities 'provided for (with reference to the regulatory framework) without entering into the merit of questions more' related to merit and the correct response to the new and urgent urban issues

c) **experimenting with innovative teaching** investigating how to leave the lot and include the context; developing a detailed description of urban fabrics; defining a design oriented to the transformation and improvement of the context in terms of sustainability and inclusiveness, and refining the arguments supporting the project. The experimentation will be completed by the third year, and can be proposed as a semi-intensive workshop of two weeks, connecting it with the design course in the first half of 2019-20, in the first two weeks of November, preceded by a part on the reading of the model workshop already experimented.

3. Some conclusions and future perspectives
